If any of you undertakes exertions of this kind, he will certainly gain a powerful impression of the wealth of evidential material. But he will also come up against a difficulty. The sense of a symptom lies, as we have found, in some connection with the patient's experience. The more individual is the form of the symptom the more reason we shall have for expecting to be able to establish this connection. The task is then simply to discover, in respect to a senseless idea and a pointless action, the past situation in which the idea was justified and the action served a purpose. The obsessional action of our patient who ran to the table and rang for the housemaid is a perfect model of this kind of symptom. But there are - and they are very frequent symptoms of quite another character. They must be described as 'typical' symptoms of an illness; they are approximately the same in all cases, individual distinctions disappear in them or at least shrink up to such an extent that it is difficult to bring them into connection with the patients' individual experience and to relate them to particular situations they have experienced. Let us look once more at obsessional neurosis. the sleep-ceremonial of our second patient already has much that is typical about it, though at the same time it has enough individual traits to make what I might call a 'historical' interpretation possible. But all these obsessional patients have a tendency to repeat, to make their performances rhythmical and to keep them isolated from other actions. The majority of them wash too much. Patients who suffer from agoraphobia (topophobia or fear of spaces), which we no longer regard as obsessional neurosis but describe as 'anxiety hysteria', often repeat the same features in their symptoms with wearisome monotony: they are afraid of enclosed spaces, of large open squares, of lengthy roads and streets. They feel protected if they are accompanied by an acquaintance or followed by a vehicle, and so on. On this similar background, however, different patients nevertheless display their individual requirements - whims, one is inclined to say - which in some cases contradict one another directly. One patient avoids only narrow streets and another only wide ones; one can go out only if there are few people in the street, another only if there are many. In the same way, hysteria, in spite of its wealth of individual traits, has a superfluity of common, typical symptoms, which seem to resist any easy historical derivation. And we must not forget that it is these typical symptoms, indeed, which give us our bearings when we make our diagnosis. Suppose, in a case of hysteria, we have really traced a typical symptom back to an experience or a chain of similar experiences - a case of hysterical vomiting, for instance, to a series of disgusting impressions - then we are at a loss when the analysis in a similar case of vomiting reveals a series of a quite different kind of ostensibly effective experiences. It looks, then, as though for unknown reasons hysterical patients are bound to produce vomiting and as though the historical precipitating causes revealed by analysis were only pretexts which, if they happen to be there, are exploited by this internal necessity.

So we are now faced by the depressing discovery that, though we can give a satisfactory explanation of the individual neurotic symptoms by their connection with experiences, our skill leaves us in the lurch when we come to the far more frequent typical symptoms. Furthermore, I am far from having made you acquainted with all the difficulties that arise when consistently pursuing the historical interpretation of symptoms. Nor do I intend to do so; for, though it is my intention not to gloss things over to you or conceal them, I cannot throw you into perplexity and confusion at the very beginning of our common studies. It is true that we have only made a beginning with our efforts at understanding the significance of symptoms; but we will hold fast to what we have achieved and pursue our way step by step to a mastery of what we have not yet understood. I will try to console you, therefore, with the reflection that any fundamental distinction between one kind of symptom and the other is scarcely to be assumed. If the individual symptoms are so unmistakably dependent on the patient's experience, it remains possible that the typical symptoms may go back to an experience which is in itself typical - common to all human beings. Other features which recur regularly in neuroses may be general reactions which are imposed on the patients by the nature of their pathological change, like the repetitions or doubts in obsessional neurosis. In short, we have no grounds for premature despair; we shall see what remains to be seen.

A quite similar difficulty faces us in the theory of dreams. I could not deal with it in our earlier discussions on dreams. The manifest content of dreams is of the greatest diversity and individual variety, and we have shown in detail what one derives from this content by means of analysis. But alongside of these there are dreams which equally deserve to be called 'typical', which happen in everyone in the same way, dreams with a uniform content, which offer the same difficulties to interpretation. They are dreams of falling, flying, floating, swimming, of being inhibited, of being naked and certain other anxiety dreams - which lead, in different people, now to this and now to that interpretation, without any light being thrown on their monotony and typical occurrence. But in these dreams too we observe that this common background is enlivened by additions that vary individually; and it is probable that, with a widening of our knowledge, it will be possible, without constraint, to include these dreams too in the understanding of dream-life which we have acquired from other dreams.

LECTURE XVIII

FIXATION TO TRAUMAS - THE UNCONSCIOUS

LADIES AND GENTLEMEN, - In my last lecture I expressed a desire that our work should go forward on the basis not of our doubts but of our discoveries. We have not yet had any discussion of two of the most interesting implications that follow from our two sample analyses.

To take the first of these. Both patients give us an impression of having been 'fixated' to a particular portion of their past, as though they could not manage to free themselves from it and were for that reason alienated from the present and the future. They then remained lodged in their illness in the sort of way in which in earlier days people retreated into a monastery in order to bear the burden there of their ill-fated lives. What had brought this fate upon our first patient was the marriage which she had in real life abandoned. By means of her symptoms she continued to carry on her dealings with her husband. We learnt to understand the voices that pleaded for him, that excused him, that put him on a pedestal and that lamented his loss. Although she was young and desirable to other men, she had taken every precaution, real and imaginary (magical), to remain faithful to him. She did not show herself to strangers and she neglected her personal appearance; furthermore, once she had sat down in a chair she was unable to get out of it quickly, she refused to sign her name, and she could not make any presents, on the ground that no one ought to receive anything from her.

The same effect was produced on the life of our second patient, the young girl, by an erotic attachment to her father which had started during the years before her puberty. The conclusion she herself drew was that she could not marry as long as she was so ill. We, however, may suspect that she had become so ill in order not to have to marry and in order to remain with her father.

We cannot dismiss the question of why, in what way and for what motive a person can arrive at such a remarkable attitude to life and one that is so inexpedient - assuming that this attitude is a general characteristic of neuroses and not a special peculiarity of these two patients. And in fact it is a general feature, of great practical importance, in every neurosis. Breuer's first hysterical patient was similarly fixated to the period when she was nursing her father in a serious illness. In spite of her recovery, in a certain respect she remained cut off from life; she remained healthy and efficient but avoided the normal course of a woman's life. In every one of our patients, analysis shows us that they have been carried back to some particular period of their past by the symptoms of their illness or their consequences. In the majority of cases, indeed, a very early phase of life is chosen for the purpose - a period of their childhood or even, laughable as this may sound, of their existence as an infant at the breast.

The closest analogy to this behaviour of our neurotics is afforded by illnesses which are being produced with special frequency precisely at the present time by the war - what are described as traumatic neuroses. Similar cases, of course, appeared before the war as well, after railway collisions and other alarming accidents involving fatal risks. Traumatic neuroses are not in their essence the same thing as the spontaneous neuroses which we are in the habit of investigating and treating by analysis; nor have we yet succeeded in bringing them into harmony with our views, and I hope I shall be able at some time to explain to you the reason for this limitation. But in one respect we may insist that there is a complete agreement between them. The traumatic neuroses give a clear indication that a fixation to the moment of the traumatic accident lies at their root. These patients regularly repeat the traumatic situation in their dreams; where hysteriform attacks occur that admit of an analysis, we find that the attack corresponds to a complete transplanting of the patient into the traumatic situation. It is as though these patients had not finished with the traumatic situation, as though they were still faced by it as an immediate task which has not been dealt with; and we take this view quite seriously. It shows us the way to what we may call an *economic* view of mental processes. Indeed, the term 'traumatic' has no other sense than an economic one. We apply it to an experience which within a short period of time presents the mind with an increase of stimulus too powerful to be dealt with or worked off in the normal way, and this must result in permanent disturbances of the manner in which the energy operates.

This analogy is bound to tempt us to describe as traumatic those experiences too to which our neurotic patients seem to be fixated. This would promise to offer us a simple determinant for the onset of neurosis. Neurosis could then be equated with a traumatic illness and would come about owing to inability to deal with an experience whose affective colouring was excessively powerful. And this indeed was actually the first formula in which (in 1893 and 1895) Breuer and I accounted theoretically for our new observations. A case like that of the first of the two patients in my last lecture - the young married woman separated from her husband - fits in very well with this view. She had not got over the failure of her marriage and remained attached to that trauma. But our second case - that of the girl with a fixation upon her father - shows us already that the formula is not sufficiently comprehensive. On the one hand, a little girl's being in love like this with her father is something so common and so frequently surmounted that the term 'traumatic' applied to it would lose all its meaning; and, on the other hand, the patient's history showed us that in the first instance her erotic fixation appeared to have passed off without doing any damage, and it was only several years later that it reappeared in the symptoms of the obsessional neurosis. Here, then, we foresee complications, a greater wealth of determinants for the onset of illness; but we may also suspect that there is no need to abandon the traumatic line of approach as being erroneous: it must be possible to fit it in and subsume it somewhere else.

Here once more, then, we must break off the course we have started on. For the moment it leads no further and we shall have to learn all kinds of other things before we can find its proper continuation. But on the subject of fixation to a particular phase in the past we may add that such behaviour is far more widespread than neurosis. Every neurosis includes a fixation of that kind, but not every fixation leads to a neurosis, coincides with a neurosis or arises owing to a neurosis. A perfect model of an affective fixation to something that is past is provided by mourning, which actually involves the most complete alienation from the present and the future. But even the judgement of a layman will distinguish sharply between mourning and neurosis. There are, on the other hand, neuroses which may be described as a pathological form of mourning.

It may happen, too, that a person is brought so completely to a stop by a traumatic event which shatters the foundations of his life that he abandons all interest in the present and future and remains permanently absorbed in mental concentration upon the past. But an unfortunate such as this need not on that account become a neurotic. We will not attach too much value to this one feature, therefore, in characterizing neurosis, however regularly present and however important it may usually be.

Let us turn now to the second of the discoveries which follow from our analyses; in its case we need not fear having to make a subsequent qualification of our views. I have described to you how our first patient carried out a senseless obsessional action and how she reported an intimate memory from her past life as having some connection with it: and how afterwards I examined the connection between the two and discovered the intention of the obsessional action from its relation to the memory. But there is one factor which I have entirely neglected, though it deserves our fullest attention. However often the patient repeated her obsessional action, she knew nothing of its being derived from the experience she had had. The connection between the two was hidden from her; she could only quite truthfully reply that she did not know what it was that was making her carry out her action. Then suddenly one day, under the influence of the treatment, she succeeded in discovering the connection and reported it to me. But she still knew nothing of the intention with which she was performing the obsessional action - the intention of correcting a distressing portion of the past and of putting her beloved husband in a better light. It took a fairly long time and called for much labour before she understood and admitted to me that such a motive alone could have been the driving force of her obsessional action.

The link with the scene after her unhappy wedding-night and the patient's affectionate motive constituted, taken together, what we have called the 'sense' of the obsessional action. But while she was carrying out the obsessional action this sense had been unknown to her in both directions - both its 'whence' and its 'whither'. Mental processes had therefore been at work in her and the obsessional action was the effect of them; she had been aware of this effect in a normal mental fashion, but none of the mental predeterminants of this effect came to the knowledge of her consciousness. She behaved in precisely the same way as a hypnotized subject whom Bernheim had ordered to open an umbrella in the hospital ward five minutes after he woke up. The man carried out this instruction when he was awake, but he could produce no motive for his action. It is a state of affairs of this sort that we have before our eyes when we speak of the existence of *unconscious mental processes*. We can challenge anyone in the world to give a more correct scientific account of this state of affairs, and if he does we will gladly renounce our hypothesis of unconscious mental processes. Till that happens, however, we will hold fast to the hypothesis; and if someone objects that here the unconscious is nothing real in a scientific sense, is a makeshift, *une façon de parler*, we can only shrug our shoulders resignedly and dismiss what he says as unintelligible. Something not real, which produces effects of such tangible reality as an obsessional action!

And we meet with what is in essence the same thing in our second patient. She had made a rule that the pillow must not touch the back of the bedstead, and she had to obey this rule though she did not know where it came from, what it meant or to what motives it owed its power. Whether she herself regarded the rule as a matter of indifference, or whether she struggled against it or raged against it or decided to transgress it - none of this made any difference to her carrying it out. It had to be obeyed, and she asked herself vainly why. We must recognize, however, that these symptoms of obsessional neurosis, these ideas and impulses which emerge one knows not whence, which prove so resistant to every influence from an otherwise normal mind, which give the patient himself the impression of being all-powerful guests from an alien world, immortal beings intruding into the turmoil of mortal life - these symptoms offer the plainest indication of there being a special region of the mind, shut off from the rest. They lead, by a path that cannot be missed, to a conviction of the existence of the unconscious in the mind; and that is precisely why clinical psychiatry, which is acquainted only with a psychology of consciousness, can deal with these symptoms in no other way than by declaring them to be signs of a special sort of degeneracy. Obsessional ideas and obsessional impulses are not, of course, themselves unconscious, any more than the performance of obsessional actions escapes conscious perception. They would not have become symptoms if they had not forced their way into consciousness. But their psychical predeterminants which we infer by means of analysis, the connections into which we insert them by interpretation, are unconscious, at least until we have made them conscious to the patient by the work of analysis.

If, now, you consider further that the state of affairs which we have established in our two cases is confirmed for every symptom of every neurotic illness - that always and everywhere the sense of the symptoms is unknown to the patient and that analysis regularly shows that these symptoms are derivatives of unconscious processes but can, subject to a variety of favourable circumstances, be made conscious - if you consider this, you will understand that in psycho-analysis we cannot do without what is at the same time unconscious and mental, and are accustomed to operate with it as though it were something palpable to the senses. But you will understand as well, perhaps, how incapable of forming a judgement on this question are all those other people, who are only acquainted with the unconscious as a concept, who have never carried out an analysis and have never interpreted dreams or found a sense and intention in neurotic symptoms. To say it for our ends once again: the possibility of giving a sense to neurotic symptoms by analytic interpretation is an unshakeable proof of the existence - or, if you prefer it, of the necessity for the hypothesis - of unconscious mental processes.

But that is not all. Thanks to a second discovery of Breuer's, which seems to me even more significant than the other and which he shared with no one, we learn still more of the connection between neurotic symptoms and the unconscious. Not only is the sense of the symptoms regularly unconscious, but there is an inseparable relation between this fact of the symptoms being unconscious and the possibility of their existing. You will understand me in a moment. I follow Breuer in asserting that every time we come upon a symptom we can infer that there are certain definite unconscious processes in the patient which contain the sense of the symptom. But it is also necessary for that sense to be unconscious in order that the symptom can come about. Symptoms are never constructed from conscious processes; as soon as the unconscious processes concerned have become conscious, the symptom must disappear. Here you will at once perceive a means of approach to therapy, a way of making symptoms disappear. And in this way Breuer did in fact restore his hysterical patient - that is, freed her from her symptoms; he found a technique for bringing to her consciousness the unconscious processes which contained the sense of the symptoms, and the symptoms disappeared.

This discovery of Breuer's was not the result of speculation but of a fortunate observation made possible by the patient's co-operation. Nor should you torment yourselves with attempts at understanding it by tracing it back to something already known; you should recognize in it a new fundamental fact, by whose help much else will become explicable. Allow me, therefore, to repeat the same thing to you in another way.

The construction of a symptom is a substitute for something else that did not happen. Some particular mental processes should normally have developed to a point at which consciousness received information of them. This, however, did not take place, and instead - out of the interrupted processes, which had been somehow disturbed and were obliged to remain unconscious - the symptom emerged. Thus something in the nature of an exchange has taken place; if this can be reversed the therapy of the neurotic symptoms will have achieved its task.

This discovery of Breuer's is still the foundation of psycho-analytic therapy. The thesis that symptoms disappear when we have made their unconscious predeterminants conscious has been confirmed by all subsequent research, although we meet with the strangest and most unexpected complications when we attempt to carry it through in practice. Our therapy works by transforming what is unconscious into what is conscious, and it works only in so far as it is in a position to effect that transformation.

And now I must quickly make a short digression, to avoid the risk of your imagining that this therapeutic work is accomplished too easily. From what I have so far said a neurosis would seem to be the result of a kind of ignorance - a not knowing about mental events that one ought to know of. This would be a close approximation to some well-known Socratic doctrines, according to which even vices are based on ignorance. Now it would as a rule be very easy for a doctor experienced in analysis to guess what mental impulses had remained unconscious in a particular patient. So it ought not to be very difficult, either, for him to restore the patient by communicating his knowledge to him and so remedying his ignorance. One part at least of the symptom's unconscious sense could be easily dealt with in this way, though it is true that the doctor cannot guess much about the other part - the connection between the symptoms and the patient's experiences -, since he himself does not know those experiences but must wait till the patient remembers them and tells them to him. But even for this a substitute can in some instances be found. One can make enquiries about these experiences from the patient's relatives and they will often be able to recognize which of them had a traumatic effect, and they can even sometimes report experiences of which the patient himself knows nothing because they occurred at a very early period of his life. Thus, by combining these two methods, we should have a prospect of relieving the patient of his pathogenic ignorance with little expense of time or trouble.

If only that was how things happened! We came upon discoveries in this connection for which we were at first unprepared. Knowledge is not always the same as knowledge: there are different sorts of knowledge, which are far from equivalent psychologically. 'Il y a fagots et fagots', as Molière has said. The doctor's knowledge is not the same as the patient's and cannot produce the same effects. If the doctor transfers his knowledge to the patient as a piece of information, it has no result. No, it would be wrong to say that. It does not have the result of removing the symptoms, but it has another one - of setting the analysis in motion, of which the first signs are often expressions of denial. The patient knows after this what he did not know before - the sense of his symptom; yet he knows it just as little as he did. Thus we learn that there is more than one kind of ignorance. We shall need to have a somewhat deeper understanding of psychology to show us in what these differences consist. But our thesis that the symptoms vanish when their sense is known remains true in spite of this. All we have to add is that the knowledge must rest on an internal change in the patient such as can only be brought about by a piece of psychical work with a particular aim. We are faced here by problems which will presently be brought together into the *dynamics* of the construction of symptoms.

I must ask now, Gentlemen, whether what I am saying to you is not too obscure and complicated. Am I not confusing you by so often taking back what I have said or qualifying it by starting up trains of thought and then dropping them? I should be sorry if that were so. But I have a strong dislike of simplifying things at the expense of truthfulness. I have no objection to your receiving the full impact of the many-sidedness and complexity of our subject; and I think, too, that it does no harm if I tell you more on every point than you can at the moment make use of. I am aware, after all, that every listener or reader puts what is presented to him into shape in his mind, shortens it and simplifies it, and selects from it what he would like to retain. Up to a certain point it is no doubt true that the more there is at one's disposal the more one is left with. Permit me to hope that, in spite of all the trimmings, you have clearly grasped the essential part of what I have told you - about the sense of symptoms, about the unconscious and about the relation between them. No doubt you have also understood that our further efforts will lead in two directions: first towards discovering how people fall ill and how they can come to adopt the neurotic attitude to life - which is a clinical problem; and secondly towards learning how the pathological symptoms develop from the determinants of the neurosis which remains a problem of mental dynamics. There must moreover be a point somewhere at which the two problems converge.

I will not go into this any further to-day. But since we still have some time to spare, I should like to direct your attention to another characteristic of our two analyses, which, once again, it will only be possible to appreciate fully later on - to the gaps in the patients' memories, their amnesias. As you have heard, the task of a psycho-analytic treatment can be expressed in this formula: its task is to make conscious everything that is pathogenically unconscious. You will perhaps be surprised to learn, then, that this formula can be replaced by another one: its task is to fill up all the gaps in the patient's memory, to remove his amnesias. This would amount to the same thing. We are thus implying that the amnesias of neurotic patients have an important connection with the origin of their symptoms. If, however, you consider the case of our first analysis you will not find this view of amnesia justified. The patient had *not* forgotten the scene from which her obsessive action was derived; on the contrary, she had a vivid recollection of it; nor did anything else forgotten play a part in the origin of the symptom. The position with our second patient (the girl with the obsessional ceremonial), though less clear, was on the whole analogous. She had not really forgotten her behaviour in earlier years - the fact that she had insisted on the door between her parents' bedroom and her own being left open and that she had driven her mother out of her place in her parents' bed; she remembered this very plainly, even though with hesitation and unwillingly. The only thing we can consider striking is that the first patient, in carrying out her obsessional action on countless occasions, had never *once* noticed its resemblance to her experience on her wedding-night, and that the memory of it did not occur to her when she was directly asked to look for the motives of her obsessional action. And the same thing applies to the girl, whose ceremonial and its causes were moreover connected with a situation which was identically repeated every evening. In both these cases there was no true amnesia, no missing memory; but a connection had been broken which ought to have led to the reproduction or re-emergence of the memory.

A disturbance of memory of this kind is enough for obsessional neurosis; but the case is different with hysteria. As a rule the latter neurosis is marked by amnesias on a really large scale. In analysing each separate hysterical symptom one is usually led to a whole chain of impressions of events, which, when they recur, are expressly described by the patient as having been till then forgotten. On the one hand, this chain reaches back to the earliest years of life, so that the hysterical amnesia can be recognized as an immediate continuation of the infantile amnesia which, for us normal people, conceals the beginnings of our mental life. On the other hand, we learn with astonishment that even the patient's most recent experiences can be subject to forgetting, and that the occasions which precipitated the outbreak of the illness or led to its intensification are in particular encroached upon, if not completely swallowed up, by amnesia. It regularly happens that important details have disappeared from the total picture of a recent recollection of this sort or that they have been replaced by falsifications of memory. Indeed it happens with almost equal regularity that certain memories of recent experiences only emerge shortly before the end of an analysis memories which had been held back till that late moment and had left perceptible gaps in the continuity of the case.

Such restrictions upon the faculty of memory are, as I have said, characteristic of hysteria, in which, indeed, states also arise as symptoms - hysterical attacks - which need leave no trace behind them in the memory. If things are different in obsessional neurosis, you may conclude that what we are dealing with in these amnesias is a psychological characteristic of the change that occurs in hysteria and is not a universal feature of neuroses in general. The importance of this distinction is reduced by the following consideration. We have comprised two things as the 'sense' of a symptom: its 'whence' and its 'whither' or 'what for' - that is, the impressions and experiences from which it arose and the intentions which it serves. Thus the 'whence' of a symptom resolves itself into impressions which came from outside, which were necessarily once conscious and may have since become unconscious through forgetting. The 'whither' of a symptom, its purpose, is invariably, however, an endopsychic process, which may possibly have been conscious at first but may equally well never have been conscious and may have remained in the unconscious from the very start. Thus it is not of great importance whether the amnesia has laid hold on the 'whence' as well - the experiences on which the symptom is supported - as happens in hysteria; it is on the 'whither', the purpose of the symptom, which may have been unconscious from the beginning, that its dependence on the unconscious is founded - and no less firmly in obsessional neurosis than in hysteria.

But in thus emphasizing the unconscious in mental life we have conjured up the most evil spirits of criticism against psycho-analysis. Do not be surprised at this, and do not suppose that the resistance to us rests only on the understandable difficulty of the unconscious or the- relative inaccessibility of the experiences which provide evidence of it. Its source, I think, lies deeper. In the course of centuries the *naïve* self-love of men has had to submit to two major blows at the hands of science. The first was when they learnt that our earth was not the centre of the universe but only a tiny fragment of a cosmic system 0; scarcely imaginable vastness. This is associated in our mind: with the name of Copernicus, though something similar had already been asserted by Alexandrian science. The second blow fell when biological research destroyed man's supposedly privileged place in creation and proved his descent from the animal kingdom and his ineradicable animal nature. This revaluation has been accomplished in our own days by Darwin, Wallace and their predecessors, though not without the most violent contemporary opposition. But human megalomania will have suffered its third and most wounding blow from the psychological research of the present time which seeks to prove to the ego that it is not even master in its own house, but must content itself with scanty information of what is going on unconsciously in its mind. We psycho-analysts were not the first and not the only ones to utter this call to introspection; but it seems to be our fate to give it its most forcible expression and to support it with empirical material which affects every individual. Hence arises the general revolt against our science, the disregard of all considerations of academic civility and the releasing of the opposition from every restraint of impartial logic. And beyond all this we have yet to disturb the peace of this world in still another way, as you will shortly hear.

LECTURE XIX

RESISTANCE AND REPRESSION

LADIES AND GENTLEMEN, - Before we can make any further progress in our understanding of the neuroses, we stand in need of some fresh observations. Here we have two such, both of which are very remarkable and at the time when they were made were very surprising. Our discussions of last year will, it is true, have prepared you for both of them.

In the first place, then, when we undertake to restore a patient to health, to relieve him of the symptoms of his illness, he meets us with a violent and tenacious resistance, which persists throughout the whole length of the treatment. This is such a strange fact that we cannot expect it to find much credence. It is best to say nothing about it to the patient's relatives, for they invariably regard it as an excuse on our part for the length or failure of our treatment. The patient, too, produces all the phenomena of this resistance without recognizing it as such, and if we can induce him to take our view of it and to reckon with its existence, that already counts as a great success. Only think of it! The patient, who is suffering so much from his symptoms and is causing those about him to share his sufferings, who is ready to undertake so many sacrifices in time, money, effort and self-discipline in order to be freed from those symptoms we are to believe that this same patient puts up a struggle in the interest of his illness against the person who is helping him. How improbable such an assertion must sound! Yet it is true; and when its improbability is pointed out to us, we need only reply that it is not without analogies. A man who has gone to the dentist because of an unbearable toothache will nevertheless try to hold the dentist back when he approaches the sick tooth with a pair of forceps.

The patient's resistance is of very many sorts, extremely subtle and often hard to detect; and it exhibits protean changes in the forms in which it manifests itself. The doctor must be distrustful and remain on his guard against it.

In psycho-analytic therapy we make use of the same technique that is familiar to you from dream-interpretation. We instruct the patient to put himself into a state of quiet, unreflecting self-observation, and to report to us whatever internal perceptions he is able to make - feelings, thoughts, memories in the order in which they occur to him. At the same time we warn him expressly against giving way to any motive which would lead him to make a selection among these associations or to exclude any of them, whether on the ground that it is too *disagreeable* or too *indiscreet* to say, or that it is too *unimportant* or *irrelevant*, or that it is *nonsensical* and need not be said. We urge him always to follow only the surface of his consciousness and to leave aside any criticism of what he finds, whatever shape that criticism may take; and we assure him that the success of the treatment, and above all its duration, depends on the conscientiousness with which he obeys this fundamental technical rule of analysis. We already know from the technique of dream-interpretation that the associations giving rise to the doubts and objections I have just enumerated are precisely the ones that invariably contain the material which leads to the uncovering of the unconscious.

The first thing we achieve by setting up this fundamental technical rule is that it becomes the target for the attacks of the resistance. The patient endeavours in every sort of way to extricate himself from its provisions. At one moment he declares that nothing occurs to him, at the next that so many things are crowding in on him that he cannot get hold of anything. Presently we observe with pained astonishment that he has given way first to one and then to another critical objection: he betrays this to us by the long pauses that he introduces into his remarks. He then admits that there is something he really cannot say - he would be ashamed to; and he allows this reason to prevail against his promise. Or he says that something has occurred to him, but it concerns another person and not himself and is therefore exempt from being reported. Or, what has now occurred to him is really too unimportant, too silly and senseless: I cannot possibly have meant him to enter into thoughts like that. So it goes on in innumerable variations, and one can only reply that 'to say everything' really does mean 'to say everything'.

One hardly comes across a single patient who does not make an attempt at reserving some region or other for himself so as to prevent the treatment from having access to it. A man, whom I can only describe as of the highest intelligence, kept silence in this way for weeks on end about an intimate love-affair, and, when he was called to account for having broken the sacred rule, defended himself with the argument that he thought this particular story was his private business. Analytic treatment does not, of course, recognize any such right of asylum. Suppose that in a town like Vienna the experiment was made of treating a square such as the Hohe Markt, or a church like St. Stephen's, as places where no arrests might be made, and suppose we then wanted to catch a particular criminal. We could be quite sure of finding him in the sanctuary. I once decided to allow a man, on whose efficiency much depended in the external world, the right to make an exception of this kind because he was bound under his oath of office not to make communications about certain things to another person. He, it is true, was satisfied with the outcome; but I was not. I determined not to repeat an attempt under such conditions.

Obsessional neurotics understand perfectly how to make the technical rule almost useless by applying their over-conscientiousness and doubts to it. Patients suffering from anxiety hysteria occasionally succeed in carrying the rule *ad absurdum* by producing only associations which are so remote from what we are in search of that they contribute nothing to the analysis. But it is not my intention to induct you into the handling of these technical difficulties. It is enough to say that in the end, through resolution and perseverance, we succeed in extorting a certain amount of obedience to the fundamental technical rule from the resistance - which thereupon jumps over to another sphere.

It now appears as an *intellectual* resistance, it fights by means of arguments and exploits all the difficulties and improbabilities which normal but uninstructed thinking finds in the theories of analysis. It is now our fate to hear from this single voice all the criticisms and objections which assail our ears in a chorus in the scientific literature of the subject. And for this reason none of the shouts that reach us from outside sound unfamiliar. It is a regular storm in a tea-cup. But the patient is willing to be argued with; he is anxious to get us to instruct him, teach him, contradict him, introduce him to the literature, so that he can find further instruction. He is quite ready to become an adherent of psycho-analysis - on condition that analysis spares him personally. But we recognize this curiosity as a resistance, as a diversion from our particular tasks, and we repel it. In the case of an obsessional neurotic we have to expect special tactics of resistance. He will often allow the analysis to proceed on its way uninhibited, so that it is able to shed an ever-increasing light upon the riddle of his illness. We begin to wonder in the end, however, why this enlightenment is accompanied by no practical advance, no diminution of the symptoms. We are then able to realize that resistance has withdrawn on to the doubt belonging to the obsessional neurosis and from that position is successfully defying us. It is as though the patient were saying: 'Yes, that's all very nice and interesting, and I'll be very glad to go on with it further. It would change my illness a not if it were true. But I don't in the least believe that it *is* true; and, so long as I don't believe it, it makes no difference to my illness.' Things can proceed like this for a long time, till finally one comes up against this uncommitted attitude itself, and the decisive struggle then breaks out.

Intellectual resistances are not the worst; one always remains superior to them. But the patient also knows how to put up resistances, without going outside the framework of the analysis, the overcoming of which is among the most difficult of technical problems. Instead of remembering, he *repeats* attitudes and emotional impulses from his early life which can be used as a resistance against the doctor and the treatment by means of what is known as 'transference'. If the patient is a man, he usually extracts this material from his relation to his father, into whose place he fits the doctor, and in that way he makes resistances out of his efforts to become independent in himself and in his judgements, out of his ambition, the first aim of which was to do things as well as his father or to get the better of him, or out of his unwillingness to burden himself for the second time in his life with a load of gratitude. Thus at times one has an impression that the patient has entirely replaced his better intention of making an end to his illness by the alternative one of putting the doctor in the wrong, of making him realize his impotence and of triumphing over him. Women have a masterly gift for exploiting an affectionate, erotically tinged transference to the doctor for the purposes of resistance. If this attachment reaches a certain height, all their interest in the immediate situation in the treatment and all the obligations they undertook at its commencement vanish; their jealousy, which is never absent, and their exasperation at their inevitable rejection, however considerably expressed, are bound to have a damaging effect on their personal understanding with the doctor and so to put out of operation one of the most powerful motive forces of the analysis.

Resistances of this kind should not be one-sidedly condemned. They include so much of the most important material from the patient's past and bring it back in so convincing a fashion that they become some of the best supports of the analysis if a skilful technique knows how to give them the right turn. Nevertheless, it remains a remarkable fact that this material is always in the service of the resistance to begin with and brings to the fore a *façade* that is hostile to the treatment. It may also be said that what is being mobilized for fighting against the alterations we are striving for are character-traits, attitudes of the ego. In this connection we discover that these character-traits were formed in relation to the determinants of the neurosis and in reaction against its demands, and we come upon traits which cannot normally emerge, or not to the same extent, and which may be described as latent. Nor must you get an impression that we regard the appearance of these resistances as an unforeseen risk to analytic influence. No, we are aware that these resistances are bound to come to light; in fact we are dissatisfied if we cannot provoke them clearly enough and are unable to demonstrate them to the patient. Indeed we come finally to understand that the overcoming of these resistances is the essential function of analysis and is the only part of our work which gives us an assurance that we have achieved something with the patient.

If you further consider that the patient makes all the chance events that occur during his analysis into interferences with it, that he uses as reasons for slackening his efforts every diversion outside the analysis, every comment by a person of authority in his environment who is hostile to analysis, any chance organic illness or any that complicates his neurosis and, even, indeed, every improvement in his condition - if you consider all this, you will have obtained an approximate, though still in complete, picture of the forms and methods of the resistance, the struggle against which accompanies every analysis.

I have treated this point in such great detail because I must now inform you that this experience of ours with the resistance of neurotics to the removal of their symptoms became the basis of our dynamic view of the neuroses. Originally Breuer and I myself carried out psychotherapy by means of hypnosis; Breuer's first patient was treated throughout under hypnotic influence, and to begin with I followed him in this. I admit that at that period the work proceeded more easily and pleasantly, and also in a much shorter time. But results were capricious and not lasting; and for that reason I finally dropped hypnosis. And I then understood that an insight into the dynamics of these illnesses had not been possible so long as hypnosis was employed. That state was precisely able to withhold the existence of the resistance from the doctor's perception. It pushed the resistance back, making a certain area free for analytic work, and dammed it up at the frontiers of that area in such a way as to be impenetrable, just as doubt does in obsessional neurosis. For that reason I have been able to say that psycho-analysis proper began when I dispensed with the help of hypnosis.

If, however, the recognition of resistance has become so important, we should do well to find room for a cautious doubt whether we have not been too light-heartedly assuming resistances. Perhaps there really are cases of neurosis in which associations fail for other reasons, perhaps the arguments against our hypotheses really deserve to have their content examined, and perhaps we are doing patients an injustice in so conveniently setting aside their intellectual criticisms as resistance. But, Gentlemen, we did not arrive at this judgement lightly. We have had occasion to observe all these critical patients at the moment of the emergence of a resistance and after its disappearance. For resistance is constantly altering its intensity during the course of a treatment; it always increases when we are approaching a new topic, it is at its most intense while we are at the climax of dealing with that topic, and it dies away when the topic has been disposed of. Nor do we ever, unless we have been guilty of special clumsiness in our technique, have to meet the full amount of resistance of which a patient is capable. We have therefore been able to convince ourselves that on countless occasions in the course of his analysis the same man will abandon his critical attitude and then take it up again. If we are on the point of bringing a specially distressing piece of unconscious material to his consciousness, he is extremely critical; he may previously have understood and accepted a great deal, but now it is just as though those acquisitions have been swept away; in his efforts for opposition at any price, he may offer a complete picture of someone who is an emotional imbecile. But if we succeed in helping him to overcome this new resistance, he recovers his insight and understanding. Thus his critical faculty is not an independent function, to be respected as such, it is the tool of his emotional attitudes and is directed by his resistance. If there is something he does not like, he can put up a shrewd fight against it and appear highly critical; but if something suits his book, he can, on the contrary, show himself most credulous. Perhaps none of us are very different; a man who is being analysed only reveals this dependence of the intellect upon emotional life so clearly because in analysis we are putting such great pressure on him.

How, then, do we account for our observation that the patient fights with such energy against the removal of his symptoms and the setting of his mental processes on a normal course? We tell ourselves that we have succeeded in discovering powerful forces here which oppose any alteration of the patient's condition; they must be the same ones which in the past brought this condition about. During the construction of his symptoms something must have taken place which we can now reconstruct from our experiences during the *resolution* of his symptoms. We already know from Breuer's observation that there is a precondition for the existence of a symptom: some mental process must not have been brought to an end normally - so that it could become conscious. The symptom is a substitute for what did not happen at that point. We now know the point at which we must locate the operation of the force which we have surmised. A violent opposition must have started against the entry into consciousness of the questionable mental process, and for that reason it remained unconscious. As being something unconscious, it had the power to construct a symptom. This same opposition, during psycho. analytic treatment, sets itself up once more against our effort to transform what is unconscious into what is conscious. This is what we perceive as resistance. We have proposed to give the pathogenic process which is demonstrated by the resistance the name of *repression*.

We must now form more definite ideas about this process of repression. It is the precondition for the construction of symptoms; but it is also something to which we know nothing similar. Let us take as our model an impulse, a mental process that endeavours to turn itself into an action. We know that it can be repelled by what we term a rejection or condemnation. When this happens, the energy at its disposal is withdrawn from it; it becomes powerless, though it can persist as a memory. The whole process of coming to a decision about it runs its course within the knowledge of the ego. It is a very different matter if we suppose that the same impulse is subjected to repression. In that case it would retain its energy and no memory of it would remain behind; moreover the process of repression would be accomplished unnoticed by the ego. This comparison, therefore, brings us no nearer to the essential nature of repression.

I will put before you the only theoretical ideas which have proved of service for giving a more definite shape to the concept of repression. It is above all essential for this purpose that we should proceed from the purely descriptive meaning of the word 'unconscious' to the systematic meaning of the same word. That is, we will decide to say that the fact of a psychical process being conscious or unconscious is only one of its attributes and not necessarily an unambiguous one. If a process of this kind has remained unconscious, its being kept away from consciousness may perhaps only be an indication of some vicissitude it has gone through, and not that vicissitude itself. In order to form a picture of this vicissitude, let us assume that every mental process - we must admit one exception, which we shall mention at a later stage exists to begin with in an unconscious stage or phase and that it is only from there that the process passes over into the conscious phase, just as a photographic picture begins as a negative and only becomes a picture after being turned into a positive. Not every negative, however, necessarily becomes a positive; nor is it necessary that every unconscious mental process should turn into a conscious one. This may be advantageously expressed by saying that an individual process belongs to begin with to the system of the unconscious and can then, in certain circumstances, pass over into the system of the conscious.

The crudest idea of these systems is the most convenient for us - a spatial one. Let us therefore compare the system of the unconscious to a large entrance hall, in which the mental impulses jostle one another like separate individuals. Adjoining this entrance hall there is a second, narrower, room - a kind of drawing-room - in which consciousness, too, resides. But on the threshold between these two rooms a watchman performs his function: he examines the different mental impulses, acts as a censor, and will not admit them into the drawing-room if they displease him. You will see at once that it does not make much difference if the watchman turns away a particular impulse at the threshold itself or if he pushes it back across the threshold after it has entered the drawing-room. This is merely a question of the degree of his watchfulness and of how early he carries out his act of recognition. If we keep to this picture, we shall be able to extend our nomenclature further. The impulses in the entrance hall of the unconscious are out of sight of the conscious, which is in the other room; to begin with they must remain unconscious. If they have already pushed their way forward to the threshold and have been turned back by the watchman, then they are inadmissible to consciousness; we speak of them as *repressed*. But even the impulses which the watchman has allowed to cross the threshold are not on that account necessarily conscious as well; they can only become so if they succeed in catching the eye of consciousness. We are therefore justified in calling this second room the system of the *preconscious*. In that case becoming conscious retains its purely descriptive sense. For any particular impulse, however, the vicissitude of repression consists in its not being allowed by the watchman to pass from the system of the unconscious into that of the preconscious. It is the same watchman whom we get to know as resistance when we try to lift the repression by means of the analytic treatment.

Now I know you will say that these ideas are both crude and fantastic and quite impermissible in a scientific account. I know that they are crude: and, more than that, I know that they are incorrect, and, if I am not very much mistaken, I already have something better to take their place. Whether it will seem to you equally fantastic I cannot tell. They are preliminary working hypotheses, like Ampère's manikin swimming in the electric current, and they are not to be despised in so far as they are of service in making our observations intelligible. I should like to assure you that these crude hypotheses of the two rooms, the watchman at the threshold between them and consciousness as a spectator at the end of the second room, must nevertheless be very far-reaching approximations to the real facts. And I should like to hear you admit that our terms, 'unconscious', 'preconscious' and 'conscious', prejudge things far less and are far easier to justify than others which have been proposed or are in use, such as 'subconscious', 'paraconscious', 'intraconscious' and the like.

It will therefore be of greater importance to me if you warn me that an arrangement of the mental apparatus, such as I have here assumed in order to explain neurotic symptoms, must necessarily claim general validity and must give us information about normal functioning as well. You will, of course, be quite right in this. At the moment we cannot pursue this implication further; but our interest in the psychology of the forming of symptoms cannot but be increased to an extraordinary extent if there is a prospect, through the study of pathological conditions, of obtaining access to the normal mental events which are so well concealed.

Perhaps you recognize, moreover, what it is that supports our hypotheses of the two systems, and their relation to each other and to consciousness? After all, the watchman between the unconscious and the preconscious is nothing else than the *censorship*, to which, as we found, the form taken by the manifest dream is subject. The day's residues, which we recognized as the instigators of the dream, were preconscious material which, at night-time and in the state of sleep, had been under the influence of unconscious and repressed wishful impulses; they had been able, in combination with those impulses and thanks to their energy, to construct the latent dream. Under the dominance of the unconscious system this material had been worked over (by condensation and displacement) in a manner which is unknown or only exceptionally permissible in normal mental life - that is, in the preconscious system. We came to regard this difference in their manner of operating as what characterizes the two systems; the relation which the preconscious has to consciousness was regarded by us merely as an indication of its belonging to one of the two systems. Dreams are not pathological phenomena; they can appear in any healthy person under the conditions of a state of sleep. Our hypothesis about the structure of the mental apparatus, which allows us to understand the formation alike of dreams and of neurotic symptoms, has an incontrovertible claim to being taken into account in regard to normal mental life as well.

That much is what we have to say for the moment about repression. But it is only the *precondition* for the construction of symptoms. Symptoms, as we know, are a substitute for something that is held back by repression. It is a long step further, however, from repression to an understanding of this substitutive structure. On this other side of the problem, these questions arise out of our observation of repression: what kind of mental impulses are subject to repression? by what forces is it accomplished? and for what motives? So far we have only one piece of information on these points. In investigating resistance we have learnt that it emanates from forces of the ego, from known and latent character traits. It is these too, therefore, that are responsible for repression, or at any rate they have a share in it. We know nothing more at present.

At this point the second of the two observations which I mentioned to you earlier comes to our help. It is quite generally the case that analysis allows us to arrive at the intention of neurotic symptoms. This again will be nothing new to you. I have already demonstrated it to you in two cases of neurosis. But, after all, what do two cases amount to? You are right to insist on its being demonstrated to you in two hundred cases - in countless cases. The only trouble is that I cannot do that. Once again, your own experience must serve instead, or your belief, which on this point can appeal to the unanimous reports of all psycho-analysts.

You will recollect that, in the two cases whose symptoms we submitted to a detailed investigation, the analysis initiated us into these patients' most intimate sexual life. In the first case we further recognized with particular clarity the intention or purpose of the symptom we were examining; in the second case this was perhaps somewhat concealed by a factor which will be mentioned later. Well, every other case that we submit to analysis would show us the same thing that we have found in these two examples. In every instance we should be introduced by the analysis into the patient's sexual experiences and wishes; and in every instance we should be bound to see that the symptoms served the same intention. We find that this intention is the satisfaction of sexual wishes; the symptoms serve for the patients' sexual satisfaction; they are a substitute for satisfaction of this kind, which the patients are without in their lives.

Think of our first patient's obsessional action. The woman was without her husband, whom she loved intensely but with whom she could not share her life on account of his deficiencies and weaknesses. She had to remain faithful to him; she could not put anyone else in his place. Her obsessional symptom gave her what she longed for, set her husband on a pedestal, denied and corrected his weaknesses and above all his impotence. This symptom was fundamentally a wish-fulfilment, just like a dream - and moreover, what is not always true of a dream, an *erotic* wish-fulfilment. In the case of our second patient you could at least gather that her ceremonial sought to obstruct intercourse between her parents or prevent it from producing a new baby. You will also probably have guessed that it was at bottom endeavouring to put her herself in her mother's place. Once again, therefore, a setting-aside of interferences with sexual satisfaction and a fulfilment of the patient's own sexual wishes. I shall soon come to the complication I have hinted at.

I should like to anticipate, Gentlemen, the qualifications which I shall have to make later in the universal validity of these statements. I will therefore point out to you that all I have said here about repression and the formation and meaning of symptoms was derived from three forms of neurosis - anxiety hysteria, conversion hysteria and obsessional neurosis - and that in the first instance it is also valid only for these forms. These three disorders, which we are accustomed to group together as '*transference neuroses*', also circumscribe the region in which psycho-analytic therapy can function. The other neuroses have been far less thoroughly studied by psycho-analysis; in one group of them the impossibility of therapeutic influence has been a reason for this neglect. Nor should you forget that psycho-analysis is still a very young science, that preparing for it costs much trouble and time, and that not at all long ago it was being practised single-handed. Nevertheless, we are every where on the point of penetrating to an understanding of these other disorders which are not transference neuroses. I hope later to be able to introduce you to the extensions of our hypotheses and findings which result from adaptation to this new material, and to show you that these further studies have not led to contradictions but to the establishment of higher unities. If, then, everything I am saying here applies to the transference neuroses, let me first increase the value of symptoms by a new piece of information. For a comparative study of the determining causes of falling ill leads to a result which can be expressed in a formula: these people fall ill in one way or another of *frustration*, when reality prevents them from satisfying their sexual wishes. You see how excellently these two findings tally with each other. It is only thus that symptoms can be properly viewed as substitutive satisfactions for what is missed in life.

No doubt all kinds of objections can still be raised to the assertion that neurotic symptoms are substitutes for sexual satisfactions. I will mention two of them to-day. When you yourselves have carried out analytic examinations of a considerable number of neurotics, you will perhaps tell me, shaking your head, that in a lot of cases my assertion is simply not true; the symptoms seem rather to have the contrary purpose of excluding or of stopping sexual satisfaction. I will not dispute the correctness of your interpretation. The facts in psycho-analysis have a habit of being rather more complicated than we like. If they were as simple as all that, perhaps it might not have needed psycho-analysis to bring them to light. Indeed, some of the features of our second patient's ceremonial show signs of this ascetic character with its hostility to sexual satisfaction: when, for instance, she got rid of the clocks and watches, which had the magical meaning of avoiding erections during the night, or when she tried to guard against flower-pots falling and breaking, which was equivalent to protecting her virginity. In some other cases of bed ceremonials, which I have been able to analyse, this negative character was far more outspoken; the ceremonial might consist exclusively of defensive measures against sexual memories and temptations. However, we have already found often enough that in psycho-analysis opposites imply no contradiction. We might extend our thesis and say that symptoms aim either at a sexual satisfaction or at fending it off, and that on the whole the positive, wish-fulfilling character prevails in hysteria and the negative, ascetic one in obsessional neurosis. If symptoms can serve the purpose both of sexual satisfaction and of its opposite, there is an excellent basis for this double-sidedness or polarity in a part of their mechanism which I have so far not been able to mention. For, as we shall hear, they are the products of a compromise and arise from the mutual interference between two opposing currents; they represent not only the repressed but also the repressing force which had a share in their origin. One side or the other may be more strongly represented; but it is rarely that one influence is entirely absent. In hysteria a convergence of both intentions in the same symptom is usually achieved. In obsessional neurosis the two portions are often separated; the symptom then becomes diphasic and consists in two actions, one after the other, which cancel each other out.

We shall not be able to dismiss a second objection so easily. If you survey a fairly long series of interpretations of symptoms, you will probably start by judging that the concept of a substitutive sexual satisfaction has been stretched to its extreme limits in them. You will not fail to emphasize the fact that these symptoms offer nothing real in the way of satisfaction, that often enough they are restricted to the revival of a sensation or the representation of a phantasy derived from a sexual complex. And you will further point out that these supposed sexual satisfactions often take on a childish and discreditable form, approximate to an act of masturbation perhaps, or recall dirty kinds of naughtiness which are forbidden even to children - habits of which they have been broken. And, going on from this, you will also express surprise that we are representing as a sexual satisfaction what would rather have to be described as the satisfaction of lusts that are cruel or horrible or would even have to be called unnatural. We shall come to no agreement, Gentlemen, on this latter point till we have made a thorough investigation of the sexual life of human beings and till, in doing so, we have decided what it is that we are justified in calling 'sexual'.

LECTURE XX

THE SEXUAL LIFE OF HUMAN BEINGS

LADIES AND GENTLEMEN, - One would certainly have supposed that there could be no doubt as to what is to be understood by 'sexual'. First and foremost, what is sexual is something improper, something one ought not to talk about. I have been told that the pupils of a celebrated psychiatrist made an attempt once to convince their teacher of how frequently the symptoms of hysterical patients represent sexual things. For this purpose they took him to the bedside of a female hysteric, whose attacks were an unmistakable imitation of the process of childbirth. But with a shake of his head he remarked: 'Well, there's nothing sexual about childbirth.' Quite right. Childbirth need not in every case be something improper.

I see that you take offence at my joking about such serious things. But it is not altogether a joke. Seriously, it is not easy to decide what is covered by the concept 'sexual'. Perhaps the only suitable definition would be 'everything that is related to the distinction between the two sexes'. But you will regard that as colourless and too comprehensive. If you take the fact of the sexual act as the central point, you will perhaps define as sexual everything which, with a view to obtaining pleasure, is concerned with the body, and in particular with the sexual organs, of someone of the opposite sex, and which in the last resort aims at the union of the genitals and the performance of the sexual act. But if so you will really not be very far from the equation of what is sexual with what is improper, and childbirth will really not be anything sexual. If, on the other hand, you take the reproductive function as the nucleus of sexuality, you risk excluding a whole number of things which are not aimed at reproduction but which are certainly sexual, such as masturbation and perhaps even kissing. But we are already prepared to find that attempts at a definition always lead to difficulties; so let us renounce the idea of doing better in this particular case. We may suspect that in the course of the development of the concept 'sexual' something has happened which has resulted in what Silberer has aptly called an 'error of superimposition'.

On the whole, indeed, when we come to think of it, we are not quite at a loss in regard to what it is that people call sexual. Something which combines a reference to the contrast between the sexes, to the search for pleasure, to the reproductive function and to the characteristic of something that is improper and must be kept secret - some such combination will serve for all practical purposes in everyday life. But for science that is not enough. By means of careful investigations (only made possible, indeed, by disinterested self-discipline) we have come to know groups of individuals whose 'sexual life' deviates in the most striking way from the usual picture of the average. Some of these 'perverse' people have, we might say, struck the distinction between the sexes off their programme. Only members of their own sex can rouse their sexual wishes; those of the other sex, and especially their sexual parts, are not a sexual object for them at all, and in extreme cases are an object of disgust. This implies, of course, that they have abandoned any share in reproduction. We call such people homosexuals or invert. They are men and women who are often, though not always, irreproachably fashioned in other respects, of high intellectual and ethical development, the victims only of this one fatal deviation. Through the mouth of their scientific spokesmen they represent themselves as a special variety of the human species - a 'third sex' which has a right to stand on an equal footing beside the other two. We shall perhaps have an opportunity of examining their claims critically. Of course they are not, as they also like to assert, an '*elite*' of mankind; there are at least as many inferior and useless individuals among them as there are among those of a different sexual kind.

This class of perverts at any rate behave to their sexual objects in approximately the same way as normal people do to theirs. But we now come to a long series of abnormal people whose sexual activity diverges more and more widely from what seems desirable to a sensible person. In their multiplicity and strangeness they can only be compared to the grotesque monsters painted by Breughel for the temptation of St. Anthony or to the long procession of vanished gods and believers which Flaubert heads past, before the eyes of his pious penitent. Such a medley calls for some kind of arrangement if it is not to confuse our senses. We accordingly divide them into those in whom, like the homosexuals, the sexual *object* has been changed, and others in whom the sexual *aim* is what has primarily been altered. The first group includes those who have renounced the union of the two genitals and who replace the genitals of one of the couple engaged in the sexual act by some other part or region of the body; in this they disregard the lack of suitable organic arrangements as well as any impediment offered by feelings of disgust. (They replace the vulva, for instance, by the mouth or anus.) Others follow, who, it is true, still retain the genitals as an object - not, however, on account of their sexual function but of other functions in which the genital plays a part either for anatomical reasons or because of its propinquity. We find from them that the excretory functions, which have been put aside as improper during the upbringing of children, retain the ability to attract the whole of sexual interest. Then come others again, who have abandoned the genital as an object altogether, and have taken some other part of the body as the object they desire - a woman's breast, a foot or a plait of hair. After them come others for whom parts of the body are of no importance but whose every wish is satisfied by a piece of clothing, a shoe, a piece of underclothing - the fetishists. Later in the procession come people who require the whole object indeed, but make quite definite demands of it - strange or horrible - even that it must have become a defenceless corpse, and who, using criminal violence, make it into one so that they may enjoy it. But enough of this kind of horror!

The second group is led by perverts who have made what is normally only an introductory or preparatory act into the aim of their sexual wishes. They are people whose desire it is to look at the other person or to feel him or to watch him in the performance of his intimate actions, or who expose parts of their own bodies which should be covered, in the obscure expectation that they may be rewarded by a corresponding action in return. Next come the sadists, puzzling people whose tender endeavours have no other aim than to cause pain and torment to their object, ranging from humiliation to severe physical injuries; and, as though to counterbalance them, their counterparts, the masochists, whose only pleasure it is to suffer humiliations and torments of every kind from their loved object either symbolically or in reality. There are still others in whom several of these abnormal preconditions are united and intertwined; and lastly, we must learn that each of these groups is to be found in two forms: alongside of those who seek their sexual satisfaction in reality are those who are content merely to *imagine* that satisfaction, who need no real object at all, but can replace it by their phantasies.

Now there cannot be the slightest doubt that all these crazy, eccentric and horrible things really constitute the sexual activity of these people. Not only do they themselves regard them as such and are aware that they are substitutes for each other, but we must admit that they play the same part in their lives as normal sexual satisfaction does in ours; they make the same, often excessive sacrifices for them, and we can trace both in the rough and in finer detail the points at which these abnormalities are based on what is normal and the points at which they diverge from it. Nor can you fail to notice that here once again you find the characteristic of being improper, which clings to sexual activity, though here it is for the most part intensified to the point of being abominable.

Well, Ladies and Gentlemen, what attitude are we to adopt to these unusual kinds of sexual satisfaction? Indignation, an expression of our personal repugnance and an assurance that we ourselves do not share these lusts will obviously be of no help. Indeed, that is not what we have been asked for. When all is said and done, what we have here is a field of phenomena like any other. A denial in the form of an evasive suggestion that after all these are only rarities and curiosities would be easy to refute. On the contrary, we are dealing with quite common and widespread phenomena. If, however, it is argued that we need not allow our views of sexual life to be misled by them because they are one and all aberrations and deviations of the sexual instinct, a serious answer is called for. Unless we can understand these pathological forms of sexuality and can co-ordinate them with normal sexual life, we cannot understand normal sexuality either. In short, it remains an unavoidable task to give a complete theoretical account of how it is that these perversions can occur and of their connection with what is described as normal sexuality.

We shall be helped in this by a piece of information and two fresh observations. We owe the former to Iwan Bloch. It corrects the view that all these perversions are 'signs of degeneracy' by showing that aberrations of this kind from the sexual aim, loosening like these of the tie with the sexual object, have occurred from time immemorial, in all periods known to us, among all peoples, the most primitive and the most civilized, and have occasionally obtained toleration and general recognition. The two observations were derived from the psycho-analytic investigation of neurotics; they are bound to have a decisive influence on our view of the sexual perversions.

I have said that neurotic symptoms are substitutes for sexual satisfaction, and I indicated to you that the confirmation of this assertion by the analysis of symptoms would come up against a number of difficulties. For it can only be justified if under 'sexual satisfaction' we include the satisfaction of what are called perverse sexual needs, since an interpretation of symptoms of that kind is forced upon us with surprising frequency. The claim made by homosexuals or inverts to being exceptions collapses at once when we learn that homosexual impulses are invariably discovered in every single neurotic, and that a fair number of symptoms give expression to this latent inversion. Those who call themselves homosexuals are only the conscious and manifest inverts, whose number is nothing compared to that of the *latent* homosexuals. We are compelled, however, to regard choice of an object of one's own sex as a divergence in erotic life which is of positively habitual occurrence, and we are learning more and more to ascribe an especially high importance to it. No doubt this does not do away with the differences between manifest homosexuality and a normal attitude; their practical significance remains, but their theoretical value is greatly diminished. We have even found that a particular disease, paranoia, which is not to be counted among the transference neuroses, regularly arises from an attempt to fend off excessively strong homosexual impulses. You will perhaps recall that one of our patients (p. 3343) behaved in her obsessional action like a man, her own husband whom she had left; neurotic women very commonly produce symptoms in this way in the character of a man. Even if this is not actually to be regarded as homosexuality, it is closely related to its preconditions.

As you probably know, the hysterical neurosis can produce its symptoms in any system of organs and so disturb any function. Analysis shows that in this way all the so-called perverse impulses which seek to replace the genital by some other organ manifest themselves: these organs are then behaving like substitutive genitals. The symptoms of hysteria have actually led us to the view that the bodily organs, besides the functional part they play, must be recognized as having a sexual (erotogenic) significance, and that the execution of the first of these tasks is disturbed if the second of them makes too many claims. Countless sensations and innervations which we come across as symptoms of hysteria in organs that have no apparent connection with sexuality are in this way revealed to us as being in the nature of fulfilments of perverse sexual impulses in relation to which other organs have acquired the significance of the sexual parts. We learn too to what a large extent the organs for the intake of nourishment and for excretion can in particular become the vehicles of sexual excitation. Here, then, we have the same thing that we were shown by the perversions; only in their case it was visible easily and unmistakably, whereas in hysteria we have to take a circuitous path by way of the interpretation of symptoms, and do not then ascribe the perverse sexual impulses concerned to the subject's consciousness but locate them in his unconscious.

Of the many symptomatic pictures in which obsessional neurosis appears, the most important turn out to be those provoked by the pressure of excessively strong sadistic sexual impulses (perverse, therefore, in their aim). The symptoms, indeed, in accordance with the structure of an obsessional neurosis, serve predominantly as a *defence* against these wishes or give expression to the struggle between satisfaction and defence. But satisfaction does not come off too badly either; it succeeds in roundabout ways in putting itself into effect in the patients' behaviour and is preferably directed against themselves and makes them into self-tormentors. Other forms of the neurosis, the brooding kinds, correspond to an excessive sexualization of actions which ordinarily have their place on the path to normal sexual satisfaction - an excessive sexualization of wanting to look or to touch or to explore. Here we have the explanation of the great importance of the fear of touching and of the obsession for washing. An unsuspectedly large proportion of obsessional actions may be traced back to masturbation, of which they are disguised repetitions and modifications; it is a familiar fact that masturbation, though a single and uniform action, accompanies the most various forms of sexual phantasying.

I should not have much difficulty in giving you a far more intimate picture of the relations between perversion and neurosis; but I think what I have already said will serve our purpose. We must however guard against being misled by what I have told you of the meaning of symptoms into over-estimating the frequency and intensity of people's perverse inclinations. It is possible, as you have heard, to fall ill of a neurosis as a result of a frustration of normal sexual satisfaction. But when a real frustration like this occurs, the need moves over on to abnormal methods of sexual excitation. You will later learn the way in which this happens. But in any case you will realize that as a result of this 'collateral' damming-back the perverse impulses must emerge more strongly than they would have if normal sexual satisfaction had met with no obstacle in the real world. More over a similar influence is to be recognized also as affecting the *manifest* perversions. In some cases they are provoked or made active if the normal satisfaction of the sexual instinct encounters too great difficulties for temporary reasons or because of permanent social regulations. In other cases, it is true, the inclination to perversions is quite independent of such favouring conditions; they are, we might say, the normal species of sexual life for those particular individuals.

For the moment, perhaps, you may have an impression that I have confused rather than explained the relation between normal and perverse sexuality. But you must bear the following consideration in mind. If it is true that increased difficulty in obtaining normal sexual satisfaction in real life, or deprivation of that satisfaction, brings out perverse inclinations in people who had not shown any previously, we must suppose that there was something in these people which came half-way to meet the perversions; or, if you prefer it, the perversions must have been present in them in a latent form.

And this brings us to the second novelty that I announced to you. For psycho-analytic research has had to concern itself, too, with the sexual life of children, and this is because the memories and associations arising during the analysis of symptoms regularly led back to the early years of childhood. What we inferred from these analyses was later confirmed point by point by direct observations of children. And it then turned out that all these inclinations to perversion had their roots in childhood, that children have a predisposition to all of them and carry them out to an extent corresponding to their immaturity - in short, that perverse sexuality is nothing else than a magnified infantile sexuality split up into its separate impulses.

At all events you will now see the perversions in a new light and no longer fail to realize their connection with the sexual life of human beings: but at the price of what surprises and of what feelings of distress over these incongruities! No doubt you will feel inclined at first to deny the whole business: the fact that children have anything that can be described as sexual life, the correctness of our observations and the justification for finding any kinship between the behaviour of children and what is later condemned as perversion. So allow me to begin by explaining to you the motives for your opposition, and then to present you with the sum of our observations. To suppose that children have no sexual life - sexual excitations and needs and a kind of satisfaction - but suddenly acquire it between the ages of twelve and fourteen, would (quite apart from any observations) be as improbable, and indeed senseless, biologic ally as to suppose that they brought no genitals with them into the world and only grew them at the time of puberty. What *does* awaken in them at this time is the reproductive function, which makes use for its purposes of physical and mental material already present. You are committing the error of con fusing sexuality and reproduction and by doing so you are blocking your path to an understanding of sexuality, the perversions and the neuroses. This error is, however, a tendentious one. Strangely enough, it has its source in the fact that you yourselves were once children and, while you were children, came under the influence of education. For society must undertake as one of its most important educative tasks to tame and restrict the sexual instinct when it breaks out as an urge to reproduction, and to subject it to an individual will which is identical with the bidding of society. It is also concerned to postpone the full development of the instinct till the child shall have reached a certain degree of intellectual maturity, for, with the complete irruption of the sexual instinct, educability is for practical purposes at an end. Otherwise, the instinct would break down every dam and wash away the laboriously erected work of civilization. Nor is the task of taming it ever an easy one; its success is sometimes too small, sometimes too great. The motive of human society is in the last resort an economic one; since it does not possess enough provisions to keep its members alive unless they work, it must restrict the number of its members and divert their energies from sexual activity to work. It is faced, in short, by the eternal, *primaeval* exigencies of life, which are with us to this day.

Experience must no doubt have taught the educators that the task of making the sexual will of the new generation tractable could only be carried out if they began to exercise their influence very early, if they did not wait for the storm of puberty but intervened already in the sexual life of children which is preparatory to it. For this reason almost all infantile sexual activities were forbidden to children and frowned upon; an ideal was set up of making the life of children asexual, and in course of time things came to the point at which people really believed they were asexual and thereafter science pronounced this as its doctrine. To avoid contradicting their belief and their intentions, people since then overlook the sexual activities of children (no mean achievement) or are content in science to take a different view of them. Children are pure and innocent, and anyone who describes them otherwise can be charged with being an infamous blasphemer against the tender and sacred feelings of mankind.

Children are alone in not falling in with these conventions. They assert their animal rights with complete *naïveté* and give constant evidence that they have still to travel the road to purity. Strangely enough, the people who deny the existence of sexuality in children do not on that account become milder in their educational efforts but pursue the manifestations of what they deny exists with the utmost severity - describing them as 'childish naughtinesses'. It is also of the highest theoretical interest that the period of life which contradicts the prejudice of an asexual childhood most glaringly - the years of a child's life up to the age of five or six - is afterwards covered in most people by the veil of amnesia which is only completely torn away by an analytic enquiry, though it has been permeable earlier for the construction of a few dreams.

I will now set out before you what is most definitely known about the sexual life of children. Let me at the same time, for convenience sake, introduce the concept of 'libido'. On the exact analogy of 'hunger', we use 'libido' as the name of the force (in this case that of the sexual instinct, as in the case of hunger that of the nutritive instinct) by which the instinct manifests itself. Other concepts, such as sexual 'excitation' and 'satisfaction', call for no explanation. You yourselves will easily perceive that the sexual activities of infants in arms are mostly a matter of interpretation, or you will probably use that as a ground of objection. These interpretations are arrived at on the basis of analytic examinations made by tracing from the symptoms backwards. In an infant the first impulses of sexuality make their appearance attached to other vital functions. His main interest is, as you know, directed to the intake of nourishment; when children fall asleep after being sated at the breast, they show an expression of blissful satisfaction which will be repeated later in life after the experience of a sexual orgasm. This would be too little on which to base an inference. But we observe how an infant will repeat the action of taking in nourishment without making a demand for further food; here, then, he is not actuated by hunger. We describe this as sensual sucking, and the fact that in doing this he falls asleep once more with a blissful expression shows us that the act of sensual sucking has in itself alone brought him satisfaction. Soon, as we know, things come to a point at which he cannot go to sleep without having sucked. A paediatrician in Budapest, Dr. Lindner, was the first to point out long ago the sexual nature of this activity. Those who are in charge of children, and who have no theoretical views on the subject, seem to form a similar judgement of sucking. They have no doubt of its only purpose being to obtain pleasure, class it as one of a child's 'naughtinesses' and compel him to abandon it by causing him distress, if he will not give it up of his own accord. Thus we learn that infants perform actions which have no purpose other than obtaining pleasure. It is our belief that they first experience this pleasure in connection with taking nourishment but that they soon learn to separate it from that accompanying condition. We can only refer this pleasure to an excitation of the areas of the mouth and lips; we call those parts of the body 'erotogenic zones' and describe the pleasure derived from sucking as a sexual one. We shall no doubt have to discuss further whether this description is justifiable.

If an infant could speak, he would no doubt pronounce the act of sucking at his mother's breast by far the most important in his life. He is not far wrong in this, for in this single act he is satisfying at once the two great vital needs. We are therefore not surprised to learn from psycho-analysis how such psychical importance the act retains all through life. Sucking at the mother's breast is the starting-point of the whole of sexual life, the unmatched prototype of every later sexual satisfaction, to which phantasy often enough recurs in times of need. This sucking involves making the mother's breast the first object of the sexual instinct. I can give you no idea of the important bearing of this first object upon the choice of every later object, of the profound effects it has in its transformations and substitutions in even the remotest regions of our sexual life. But at first the infant, in his sucking activity, gives up this object and replaces it by a part of his own body. He begins to suck his thumbs or his own tongue. In this way he makes himself independent of the consent of the external world as regards gaining pleasure, and besides this he increases it by adding the excitation of a second area of his body. The erotogenic zones are not all equally generous in yielding pleasure; it is therefore an important experience when the infant, as Lindner reports, discovers, in the course of feeling around, the specially excitable regions afforded by his genitals and so finds his way from sucking to masturbation.

In forming this opinion of sensual sucking we have already become acquainted with two decisive characteristics of infantile sexuality. It makes its appearance attached to the satisfaction of the major organic needs, and it behaves *auto-erotically* - that is, it seeks and finds its objects in the infant's own body. What has been shown most clearly in connection with the intake of nourishment is repeated in part with the excretions. We conclude that infants have feelings of pleasure in the process of evacuating urine and faeces and that they soon contrive to arrange those actions in such a way as to bring them the greatest possible yield of pleasure through the corresponding excitations of the erotogenic zones of the mucous membrane. It is here for the first time (as Lou Andreas-Salomé has subtly perceived) that they encounter the external world as an inhibiting power, hostile to their desire for pleasure, and have a glimpse of later conflicts both external and internal. An infant must not produce his excreta at whatever moment he chooses, but when other people decide that he shall. In order to induce him to forgo these sources of pleasure, he is told that everything that has to do with these functions is improper and must be kept secret. This is where he is first obliged to exchange pleasure for social respectability. To begin with, his attitude to his excreta themselves is quite different. He feels no disgust at his faeces, values them as a portion of his own body with which he will not readily part, and makes use of them as his first 'gift', to distinguish people whom he values especially highly. Even after education has succeeded in its aim of making these inclinations alien to him, he carries on his high valuation of faeces in his estimate of 'gifts' and 'money'. On the other hand he seems to regard his achievements in urinating with peculiar pride.

I know you have been wanting for a long time to interrupt me and exclaim: 'Enough of these atrocities! You tell us that defaecating is a source of sexual satisfaction, and already exploited in infancy! that faeces is a valuable substance and that the anus is a kind of genital! We don't believe all that but we do understand why paediatricians and educationists have given a wide berth to psycho-analysis and its findings.' No, Gentlemen. You have merely forgotten that I have been trying to introduce the facts of infantile sexual life to you in connection with the facts of the sexual perversions. Why should you not be aware that for a large number of adults, homosexual and heterosexual alike, the anus does really take over the role of the vagina in sexual intercourse? And that there are many people who retain a voluptuous feeling in defaecating all through their lives and describe it as being far from small? As regards interest in the act of defaecation and enjoyment ill watching someone else defaecating, you can get children themselves to confirm the fact when they are a few years older and able to tell you about it. Of course, you must not have systematically intimidated them beforehand, or they will quite understand that they must be silent on the subject. And as to the other things that you are anxious not to believe, I will refer you to the findings of analysis and of the direct observation of children and will add that it calls for real ingenuity not to see all this or to see it differently. Nor do I complain if you find the kinship between infantile sexual activity and sexual perversions something very striking. But it is in fact self-evident: if a child has a sexual life at all it is bound to be of a perverse kind; for, except for a few obscure hints, children are without what makes sexuality into the reproductive function. On the other hand, the abandonment of the reproductive function is the common feature of all perversions. We actually describe a sexual activity as perverse if it has given up the aim of reproduction and pursues the attainment of pleasure as an aim independent of it. So, as you will see, the breach and turning-point in the development of sexual life lies in its becoming subordinate to the purposes of reproduction. Everything that happens before this turn of events and equally everything that disregards it and that aims solely at obtaining pleasure is given the uncomplimentary name of 'perverse' and as such is proscribed.

Allow me, therefore, to proceed with my brief account of infantile sexuality. What I have already reported of two systems of organs might be confirmed in reference to the others. A child's sexual life is indeed made up entirely of the activities of a number of component instincts which seek, independently of one another, to obtain pleasure, in part from the subject's own body and in part already from an external object. Among these organs the genitals come into prominence very soon. There are people in whom obtaining pleasure from their own genitals, without the assistance of any other genitals or of an object, continues uninterruptedly from infantile masturbation to the unavoidable masturbation of puberty and persists for an indefinite length of time afterwards. Incidentally, the topic of masturbation is not one that can be so easily disposed of: it is something that calls for examination from many angles.

Though I am anxious to cut short this discussion still further, I must nevertheless tell you a little about the sexual researches of children: they are too characteristic of infantile sexuality and of too great significance for the symptomatology of the neuroses to be passed over. Infantile sexual researches begin very early, sometimes before the third year of life. They do not relate to the distinction between the sexes, for this means nothing to children, since they (or at any rate boys) attribute the same male genital to both sexes. If, afterwards, a boy makes the discovery of the vagina from seeing his little sister or a girl playmate, he tries, to begin with, to disavow the evidence of his senses, for he cannot imagine a human creature like himself who is without such a precious portion. Later on, he takes fright at the possibility thus presented to him; and any threats that may have been made to him earlier, because he took too intense an interest in his little organ, now produce a deferred effect. He comes under the sway of the castration complex, the form taken by which plays a great part in the construction of his character if he remains normal, in his neurosis if he falls ill, and in his resistances if he comes into analytic treatment. As regards little girls, we can say of them that they feel greatly at a disadvantage owing to their lack of a big, visible penis, that they envy boys for possessing one and that, in the main for this reason, they develop a wish to be a man - a wish that re-emerges later on, in any neurosis that may arise if they meet with a mishap in playing a feminine part. In her childhood, moreover, a girl's clitoris takes on the role of a penis entirely: it is characterized by special excitability and is the area in which auto-erotic satisfaction is obtained. The process of a girl's becoming a woman depends very much on the clitoris passing on this sensitivity to the vaginal orifice in good time and completely. In cases of what is known as sexual anaesthesia in women the clitoris has obstinately retained its sensitivity.

The sexual interest of children begins by turning, rather, to the problem of where babies come from - the same problem which underlies the question put by the Theban Sphinx - and it is most often raised by egoistic fears on the arrival of a new baby. The reply which is ready to hand in the nursery, that babies are brought by the stork, comes up against disbelief on the part even of small children far oftener than we are aware. The sense of being defrauded of the truth by the grown-ups contributes much to making children feel lonely and to developing their independence. But a child is not in a position to solve this problem by his own means. His undeveloped sexual constitution sets definite limits to his power of perception. He begins by supposing that babies come from people taking in something special in their food, nor does he know that only women can have babies. Later he becomes aware of this limitation and ceases to regard eating as the origin of babies - though the theory persists in fairy tales. When the child has grown bigger, he soon notices that his father must play some part in getting babies, but he cannot guess what. If he happens to witness a sexual act, he regards it as an attempt at subjugation, a struggle, and this is the sadistic misunderstanding of coition. But at first he does not connect this act with the coming into being of a baby. So, too, if he finds traces of blood on his mother's bed or on her underclothes, he takes it as a sign that she has been injured by his father. Still later in childhood, he no doubt suspects that the man's sexual organ has an essential share in producing babies, but the only function he can attribute to that part of the body is micturition.

From the very first, children are at one in thinking that babies must be born through the bowel; they must make their appearance like lumps of faeces. This theory is not abandoned until all anal interests have been deprived of their value, and it is then replaced by the hypothesis that the navel comes open or that the area of the breast between the nipples is where birth takes place. In this way the child in the course of his researches comes nearer to the facts about sex, or, feeling at a loss owing to his ignorance, he passes them by till, usually in the years before puberty, he is given what is as a rule a depreciatory and incomplete explanation, which often produces traumatic effects.

You will no doubt have heard, Gentlemen, that in psycho-analysis the concept of what is sexual has been unduly extended in order to support the theses of the sexual causation of the neuroses and the sexual meaning of symptoms. You are now in a position to judge for yourselves whether this extension is unjustified. We have only extended the concept of sexuality far enough to be able to comprise the sexual life of perverts and of children. We have, that is to say, given it back its true compass. What is called sexuality outside psycho-analysis relates only to a restricted sexual life, which serves the purpose of reproduction and is described as normal.

LECTURE XXI

THE DEVELOPMENT OF THE LIBIDO AND THE SEXUAL ORGANIZATIONS

GENTLEMEN, - I am under the impression that I have not succeeded in bringing home to you quite convincingly the importance of the perversions for our view of sexuality, and I should therefore like so far as I can to improve and supplement what I have said.

It is not the case that the perversions alone would have obliged us to make the change in the concept of sexuality which has brought such violent contradictions down on us. The study of infantile sexuality had even more to do with it and it was the concurrence of the two which was decisive for us. But the manifestations of infantile sexuality, however unmistakable they may be in later childhood, seem to melt into indefiniteness towards their beginnings. Anyone who chooses to disregard the history of their development and their analytic context will deny that they are of a sexual character and will attribute some undifferentiated character to them instead. You must not forget that at the moment we are not in possession of any generally recognized criterion of the sexual nature of a process, apart, once again, from a connection with the reproductive function which we must reject as being too narrow-minded. The biological criteria, such as the periodicities of twenty-three and twenty-eight days postulated by Wilhelm Fliess, are still highly debatable; the chemical characteristics of the sexual process, which we may suspect, are still awaiting discovery. On the other hand, the sexual perversions of adults are something tangible and unambiguous. As is already shown by the name by which they are universally known, they are unquestionably sexual. Whether they are described as indications of degeneracy or in any other way, no one has yet had the courage to class them as anything but phenomena of sexual life. On their account alone we are justified in asserting that sexuality and reproduction do not coincide, for it is obvious that all of them disavow the aim of reproduction.

I find a parallel here which is not uninteresting. Whereas for most people 'conscious' and 'psychical' are the same, we have been obliged to extend the concept of 'psychical' and to recognize something 'psychical' that is not 'conscious'. And in just the same way, whereas other people declare that 'sexual' and 'connected with reproduction' (or, if you prefer to put it more shortly, 'genital') are identical, we cannot avoid postulating something 'sexual' that is not 'genital' - has nothing to do with reproduction. The similarity here is only a formal one, but it is not without a deeper foundation.

But if the existence of sexual perversions is such a decisive argument in this question, why has it not long since had its effect and settled the matter? I really cannot say. I think it is connected with the fact that these sexual perversions are subject to a quite special ban, which has even affected theory and has stood in the way of the scientific consideration of them. It is as though no one could forget that they are not only something disgusting but also something monstrous and dangerous - as though people felt them as seductive, and had at bottom to fight down a secret envy of those who were enjoying them. One is reminded of the admission made by the condemnatory Landgraf in the famous *Tannhäuser* parody:

‘ Im Venusberg vergass er Ehr und Pflicht!
- Merkwürdig, unser einem passiert
so etwas nicht.’¹

In reality perverts are poor wretches, rather, who have to pay extremely dear for their hard-won satisfaction.

What makes the activity of perverts so unmistakably sexual in spite of all the strangeness of its objects and aims is the fact that as a rule an act of perverse satisfaction nevertheless ends in complete orgasm and avoidance of the genital products. This is of course only the result of the people concerned being adults. In children orgasm and genital excretion are scarcely possible; their place is taken by hints which are once more not recognized as being clearly sexual.

¹ [‘The Venusberg made him forget
Honour and Duty thus! -
Strange how these things don’t happen
To people such as us.’]

There is something else that I must add in order to complete our view of sexual perversions. However infamous they may be, however sharply they may be contrasted with normal sexual activity, quiet consideration will show that some perverse trait or other is seldom absent from the sexual life of normal people. Even a kiss can claim to be described as a perverse act, since it consists in the bringing together of two oral erotogenic zones instead of the two genitals. Yet no one rejects it as perverse; on the contrary, it is permitted in theatrical performances as a softened hint at the sexual act. But precisely kissing can easily turn into a complete perversion - if, that is to say, it becomes so intense that a genital discharge and orgasm follow upon it directly, an event that is far from rare. We can learn, too, that for one person feeling and looking at the object are indispensable preconditions of sexual enjoyment, that another person will pinch or bite at the climax of sexual excitation, that the highest pitch of excitement in lovers is not always provoked by the genitals but by some other region of the object's body, and any number of similar things besides. There is no sense in excluding people with individual traits of this kind from the class of the normal and putting them among the perverts. On the contrary, we shall recognize more and more clearly that the essence of the perversions lies not in the extension of the sexual aim, not in the replacement of the genitals, not even always in the variant choice of the object, but solely in the exclusiveness with which these deviations are carried out and as a result of which the sexual act serving the purpose of reproduction is put on one side. In so far as the perverse actions are inserted in the performance of the normal sexual act as preparatory or intensifying contributions, they are in reality not perversions at all. The gulf between normal and perverse sexuality is of course very much narrowed by facts of this kind. It is an easy conclusion that normal sexuality has emerged out of something that was in existence before it, by weeding out certain features of that material as unserviceable and collecting together the rest in order to subordinate them to a new aim, that of reproduction.

Before we make use of our familiarity with the perversions to plunge once again into the study of infantile sexuality on the basis of clearer premisses, I must draw your attention to an important difference between them. Perverse sexuality is as a rule excellently centred: all its actions are directed to an aim - usually to a single one; one component instinct has gained the upper hand in it and is either the only one observable or has subjected the others to its purposes. In that respect there is no distinction between perverse and normal sexuality other than the fact that their dominating component instincts and consequently their sexual aims are different. In both of them, one might say, a well-organized tyranny has been established, but in each of the two a different family has seized the reins of power. Infantile sexuality, on the other hand, lacks, speaking generally, any such centring and organization; its separate component instincts have equal rights, each of them goes its own way to obtaining pleasure. Both the absence and the presence of centring harmonize well, of course, with the fact that both perverse and normal sexuality have arisen out of infantile sexuality. Incidentally, there are also cases of perverse sexuality which have a much greater resemblance to the infantile kind, since in them numerous component instincts have put through (or, more correctly, have persisted in) their aims independently of one another. It is better in such cases to speak of infantilism in sexual life rather than of a perversion.

Thus forearmed we can proceed to the consideration of a suggestion which we shall certainly not be spared. 'Why', we shall be asked, 'are you so obstinate in describing as being already sexuality what on your own evidence are indefinable manifestations in childhood out of which sexual life will later develop? Why should you not be content instead with giving them a physiological description and simply say that in an infant at the breast we already observe activities, such as sensual sucking or holding back the excreta, which show us that he is striving for "organ-pleasure"? In that way you would have avoided the hypothesis, so repugnant to every feeling, of the smallest babies having a sexual life.' - Indeed, Gentlemen, I have no objection at all to organ-pleasure. I know that even the supreme pleasure of sexual union is only an organ-pleasure attached to the activity of the genitals. But can you tell me when this originally indifferent organ-pleasure acquires the sexual character which it undoubtedly possesses in the later phases of development? Do we know any more about 'organ-pleasure' than about sexuality? You will reply that it gains its sexual character precisely when the genitals begin to play their part; 'sexual' coincides with 'genital'. You will even reject the objection raised by the perversions by pointing out to me that in the majority of perversions a genital orgasm is after all aimed at, even if it is arrived at by a method other than the union of the genitals. You are certainly taking up a much stronger position in determining the characteristics of what is sexual if you knock out of it the relation to reproduction which is made untenable by the perversions and put genital activity in its place. But, if so, we are no longer far apart: it is only a question of the genital organs versus the other organs. What are you going to do, however, about the numerous experiences which show you that the genitals can be represented as regards their yield of pleasure by other organs, as in the case of kissing or of the perverse practices of voluptuaries or of the symptoms of hysteria? In that neurosis it is quite usual for signs of stimulation, sensations and innervations, and even the processes of erection, which belong properly to the genitals, to be displaced on to other, remote regions of the body - as, for instance, by transposition upwards, to the head and face. Being thus convinced that you have nothing to catch hold of for your characterization of what is sexual, you will no doubt have to make up your minds to follow my example and extend the description of being 'sexual' to the activities of early childhood, too, which strive for organ-pleasure.

And now, for my justification, there are two other considerations which I must ask you to take into account. As you know, we call the dubious and indefinable pleasurable activities of earliest childhood sexual because, in the course of analysis, we arrive at them from the symptoms after passing through indisputably sexual material. They need not necessarily themselves be sexual on that account - agreed! But take an analogous case. Suppose we had no means of observing the development from their seed of two dicotyledonous plants, the apple-tree and the bean, but that it was possible in both cases for us to trace their development backwards from the fully developed individual plant to the first seedling with two seed-leaves. The two seed leaves have a neutral appearance; they are just alike in both cases. Am I then to suppose that they are really alike, and that the specific difference between an apple-tree and a bean is only introduced into the plants later? Or is it biologically more correct to believe that this difference is already there in the seedling, although I cannot observe any distinction in the seed leaves? But we are doing the same thing when we call the pleasure in the activities of an infant-in-arms a sexual one. I cannot discuss here whether each and every organ-pleasure should be called a sexual one or whether, alongside of the sexual one, there is another which does not deserve to be so called. I know too little about organ-pleasure and its determinants; and, in view of the retrogressive character of analysis in general, I cannot feel surprised if at the very end I arrive at what are for the time being indefinable factors.

And one thing more! On the whole you will have gained very little for what you want to assert - the sexual purity of children - even if you succeed in convincing me that it would be better to regard the activities of infants-in-arms as non-sexual. For the sexual life of children is already free from all these doubts from the third year of life onwards: at about that time the genitals already begin to stir, a period of infantile masturbation - of genital satisfaction, therefore - sets in, regularly perhaps. The mental and social phenomena of sexual life need no longer be absent; the choice of an object, an affectionate preference for particular people, a decision, even, in favour of one of the two sexes, jealousy - all these have been established by impartial observations made independently of psycho-analysis and before its time, and they can be confirmed by any observer who cares to see them. You will object that you have never doubted the early awakening of affection; you have only doubted whether this affection bears a 'sexual' character. It is true that children have already learnt to conceal this between the ages of three and eight. But if you are attentive you will be able nevertheless to collect enough evidence of the 'sensual' aims of this affection, and whatever you still lack after that can easily be supplied in plenty by the investigations of analysis. The sexual aims at this period of life are intimately connected with the child's contemporary sexual researches, of which I have given you some in stances. The perverse character of some of these aims is of course dependent on the child's constitutional immaturity, for he has not yet discovered the aim that consists in the act of copulation.

From about the sixth to the eighth year of life onwards, we can observe a halt and retrogression in sexual development, which, in cases where it is most propitious culturally, deserves to be called a period of latency. The latency period may also be absent: it need not bring with it any interruption of sexual activity and sexual interests along the whole line. The majority of experiences and mental impulses before the start of the latency period now fall victim to infantile amnesia - the forgetting (already discussed by us) which veils our earliest youth from us and makes us strangers to it. The task is set us in every psycho-analysis of bringing this forgotten period back into memory. It is impossible to avoid a suspicion that the beginnings of sexual life which are included in that period have provided the motive for its being forgotten - that this forgetting, in fact, is an outcome of repression.

From the third year of life a child's sexual life shows much agreement with an adult's. It differs from the latter, as we already know, in lacking a firm organization under the primacy of the genitals, in its inevitable traits of perversion and also, of course, in the far lesser intensity of the whole trend. But from the point of view of theory the most interesting phases of sexual, or, as we will say, of libidinal, development lie earlier than this point of time. This course of development takes place so rapidly that we should probably never have succeeded in getting a firm hold of its fleeting pictures by direct observation. It was only with the help of the psycho-analytic investigation of the neuroses that it became possible to discern the still earlier phases of the development of the libido. These are nothing but constructions, to be sure, but, if you carry out psycho-analyses in practice, you will find that they are necessary and useful constructions. You will soon learn how it comes about that pathology can here put us in possession of conditions which we should inevitably overlook in a normal subject.

Accordingly, I can now describe to you the form taken by a child's sexual life before the establishment of the primacy of the genitals, preparations for which are made in the first period of infancy preceding the latency period and which is permanently organized from puberty onwards. A kind of loose organization which may be called 'pregenital' exists during this early period. During this phase what stand in the forefront are not the genital component instincts but the sadistic and anal ones. The contrast between 'masculine' and 'feminine' plays no part here as yet. Its place is taken by the contrast between 'active' and 'passive', which may be described as a precursor of the sexual polarity and which later on is soldered to that polarity, what appears to us as masculine in the activities of this phase, when we look at it from the point of view of the genital phase, turns out to be an expression of an instinct for mastery which easily passes over into cruelty. Trends with a passive aim are attached to the erotogenic zone of the anal orifice, which is very important at this period. The instincts for looking and for gaining knowledge are powerfully at work; the genitals actually play a part in sexual life only as organs for the excretion of urine. The component instincts of this phase are not without objects, but those objects do not necessarily converge into a single object. The sadistic anal organization is the immediate forerunner of the phase of genital primacy. Detailed study shows how much of it is retained in the later definitive shape of things and shows too the way in which its component instincts are compelled to take their place in the new genital organization. Behind the sadistic-anal phase of libidinal development we get a glimpse of a still earlier and more primitive stage of organization, in which the erotogenic zone of the mouth plays the chief part. As you will guess, the sexual activity of sensual sucking belongs to it. We must admire the understanding of the Ancient Egyptians who, in their art, represented children, including the God Horus, with a finger in their mouth. Only recently Abraham has given examples of the traces which this primitive oral phase leaves behind it in later sexual life.

I can well suppose, Gentlemen, that this last account of the sexual organizations has obstructed rather than instructed you, and it may be that I have once more entered too much into details. But you must have patience. What you have just heard will derive increased value for you from its later application. For the present you should keep firmly in mind that sexual life (or, as we put it, the libidinal function) does not emerge as something ready-made and does not even develop further in its own likeness, but passes through a series of successive phases which do not resemble one another; its development is thus several times repeated - like that of a caterpillar into a butterfly. The turning-point of this development is the subordination of all the component sexual instincts under the primacy of the genitals and along with this the subjection of sexuality to the reproductive function. This is preceded by a sexual life that might be described as distracted - the independent activity of the different component instincts striving for organ-pleasure. This anarchy is mitigated by abortive beginnings of 'pregenital' organizations - a sadistic-anal phase preceded by an oral one, which is perhaps the most primitive. In addition, there are the various, still incompletely known, processes which lead one stage of organization over to the subsequent and next higher one. We shall learn later what an important light is thrown on the neuroses by the fact that the libido passes through such a long course of development and one which has so many breaks in it.

To-day we will follow yet another side of this development namely the relation of the component sexual instincts to their object. Or rather, we will make a hasty survey of this development and dwell somewhat longer on one of its rather late consequences. A few of the components of the sexual instinct, there, have an object from the first and hold fast to it - for instance, the instinct for mastery (sadism) and the scopophilic and epistemophilic instincts. Others, more definitely linked to particular erotogenic zones of the body, have one to begin with only, so long as they are still attached to the non-sexual functions, and give it up when they become separated from them. Thus the first object of the oral component of the sexual instinct is the mother's breast which satisfies the infant's need for nourishment. The erotic component, which is satisfied simultaneously during the sucking, makes itself independent with the act of *sensual* sucking [*lutschen*]; it gives up the outside object and replaces it by an area of the subject's own body. The oral instinct becomes *auto-erotic*, as are the anal and other erotogenic instincts from the first. Further development, to put the matter as concisely as possible, has two aims: firstly, the abandonment of auto-erotism, the replacement of the subject's own body once more by an outside object, and secondly, the unification of the various objects of the separate instincts and their replacement by a single object. This can, of course, only be achieved if the object is again a whole body, similar to the subject's own. Nor can it be effected unless a number of the auto-erotic instinctual impulses are left behind as being unserviceable.

The processes of finding an object are fairly complex and no comprehensive account has hitherto been given of them. For our purposes it may be specially pointed out that when, in the years of childhood before puberty, the process has in some respects reached a conclusion, the object that has been found turns out to be almost identical with the first object of the oral pleasure-instinct, which was reached by attachment. Though it is not actually the mother's breast, at least it is the mother. We call the mother the first *love-object*. For we speak of love when we bring the mental side of the sexual trends into the foreground and want to force back the underlying physical or 'sensual' instinctual demands or to forget them for a moment. At the time at which the child's mother becomes his love-object the psychical work of repression has already begun in him, which is withdrawing from his knowledge awareness of a part of his sexual aims. To his choice of his mother as a love-object everything becomes attached which, under the name of the 'Oedipus complex', has attained so much importance in the psycho-analytic explanation of the neuroses and has played no less a part, perhaps, in the resistance to psycho-analysis.

Listen to this episode which occurred in the course of the present war. One of the stout disciples of psycho-analysis was stationed as medical officer on the German front somewhere in Poland. He attracted his colleagues' attention by the fact that he occasionally exercised an unexpected influence on a patient. When he was questioned, he acknowledged that he was employing the methods of psycho-analysis and declared his readiness to convey his knowledge to his colleagues. Every evening there after the medical officers of the corps, his colleagues and his superiors, came together in order to learn the secret doctrines of analysis. All went well for a while; but when he spoke to his audience about the Oedipus complex, one of his superiors rose, declared he did not believe it, that it was a vile act on the part of the lecturer to speak of such things to them, honest men who were fighting for their country and fathers of a family, and that he forbade the continuance of the lectures. That was the end of the matter. The analyst got himself transferred to another part of the front. It seems to me a bad thing, however, if a German victory requires that science shall be 'organized' in this way, and German science will not respond well to organization of such a kind.

And now you will be eager to hear what this terrible Oedipus complex contains. Its name tells you. You all know the Greek legend of King Oedipus, who was destined by fate to kill his father and take his mother to wife, who did everything possible to escape the oracle's decree and punished himself by blinding when he learned that he had none the less unwittingly committed both these crimes. I hope many of you may yourselves have felt the shattering effect of the tragedy in which Sophocles has treated the story. The work of the Athenian dramatist exhibits the way in which the long-past deed of Oedipus is gradually brought to light by an investigation ingeniously protracted and fanned into life by ever fresh relays of evidence. To this extent it has a certain resemblance to the progress of a psycho-analysis. In the course of the dialogue Jocasta, the deluded mother and wife, declares herself opposed to the continuance of the enquiry. She appeals to the fact that many people have dreamt of lying with their mothers, but that dreams should be despised. We do not despise dreams - least of all, typical dreams which occur to many people; and we do not doubt that the dream referred to by Jocasta has an intimate connection with the strange and terrifying content of the legend.

It is a surprising thing that the tragedy of Sophocles does not call up indignant repudiation in his audience - a reaction similar to that of our simple-minded army doctor but far better justified. For fundamentally it is an amoral work: it absolves men from moral responsibility, exhibits the gods as promoters of crime and shows the impotence of the moral impulses of men which struggle against crime. It might easily be supposed that the material of the legend had in view an indictment of the gods and of fate; and in the hands of Euripides, the critic and enemy of the gods, it would probably have become such an indictment. But with the devout Sophocles there is no question of an application of that kind. The difficulty is overcome by the pious sophistry that to bow to the will of the gods is the highest morality even when it promotes crime. I cannot think that this morality is a strong point of the play, but it has no influence on its effect. It is not to it that the auditor reacts but to the secret sense and content of the legend. He reacts as though by self analysis he had recognized the Oedipus complex in himself and had unveiled the will of the gods and the oracle as exalted disguises of his own unconscious. It is as though he was obliged to remember the two wishes - to do away with his father and in place of him to take his mother to wife - and to be horrified at them. And he understands the dramatist's voice as though it were saying to him: 'You are struggling in vain against your responsibility and are protesting in vain of what you have done in opposition to these criminal intentions. You are guilty, for you have not been able to destroy them; they still persist in you unconsciously.' And there is psychological truth contained in this. Even if a man has repressed his evil impulses into the unconscious and would like to tell himself afterwards that he is not responsible for them, he is nevertheless bound to be aware of this responsibility as a sense of guilt whose basis is unknown to him.

There can be no doubt that the Oedipus complex may be looked upon as one of the most important sources of the sense of guilt by which neurotics are so often tormented. But more than this: in a study of the beginnings of human religion and morality which I published in 1913 under the title of *Totem and Taboo* I put forward a suggestion that man kind as a whole may have acquired its sense of guilt, the ultimate source of religion and morality, at the beginning of its history, in connection with the Oedipus complex. I should be very glad to tell you more about this, but I had better leave it on one side. Once one has begun on that topic it is hard to break off; and we must go back to individual psychology.

What, then, can be gathered about the Oedipus complex from the direct observation of children at the time of their making their choice of an object before the latency period? Well, it is easy to see that the little man wants to have his mother all to himself, that he feels the presence of his father as a nuisance, that he is resentful if his father indulges in any signs of affection towards his mother and that he shows satisfaction when his father has gone on a journey or is absent. He will often express his feelings directly in words and promise his mother to marry her. It will be thought that this amounts to little compared to the deeds of Oedipus; but in fact it is enough, it is the same thing at root. Observation is often obscured by the circumstance that on other occasions the same child will simultaneously give evidence of great affection for his father. But contrary - or, as it is better to say, 'ambivalent' - emotional attitudes, which in adults would lead to a conflict, remain compatible with each other for a long time in children, just as later they find a permanent place beside each other in the unconscious. It will also be objected that the little boy's conduct arises from egoistic motives and gives no grounds for postulating an erotic complex: the child's mother attends to all his needs, so that he has an interest in preventing her from looking after anyone else. This also is true; but it will soon become clear that in this situation as in similar ones the egoistic interest is merely affording a point of support to which the erotic trend is attached. The little boy may show the most undisguised sexual curiosity about his mother, he may insist upon sleeping beside her at night, he may force his presence on her while she is dressing or may even make actual attempts at seducing her, as his mother will often notice and report with amusement - all of which puts beyond doubt the erotic nature of his tie with his mother. Nor must it be forgotten that the mother devotes the same attention to a little daughter without producing the same result and that the father often competes with her in looking after the boy and yet fails to gain the same significance as she does. In short, the factor of sexual preference cannot be eliminated from the situation by any criticism. From the standpoint of egoistic interest it would be simply foolish of the little man not to prefer to put up with having two people in his service rather than only one of them.

As you see, I have only described the relation of a *boy* to his father and mother. Things happen in just the same way with little girls, with the necessary changes: an affectionate attachment to her father, a need to get rid of her mother as superfluous and to take her place, a coquetry which already employs the methods of later womanhood - these offer a charming picture, especially in small girls, which makes us forget the possibly grave consequences lying behind this infantile situation. We must not omit to add that the parents themselves often exercise a determining influence on the awakening of a child's Oedipus attitude by themselves obeying the pull of sexual attraction, and that where there are several children the father will give the plainest evidence of his greater affection for his little daughter and the mother for her son. But the spontaneous nature of the Oedipus complex in children cannot be seriously shaken even by this factor.

When other children appear on the scene the Oedipus complex is enlarged into a family complex. This, with fresh support from the egoistic sense of injury, gives grounds for receiving the new brothers or sisters with repugnance and for unhesitatingly getting rid of them by a wish. It is even true that as a rule children are far readier to give verbal expression to *these* feelings of hate than to those arising from the parental complex. If a wish of this kind is fulfilled and the undesired addition to the family is removed again shortly afterwards by death, we can discover from a later analysis what an important experience this death has been to the child, even though it need not have remained fixed in his memory. A child who has been put into second place by the birth of a brother or sister, and who is now for the first time almost isolated from his mother, does not easily forgive her this loss of place; feelings which in an adult would be described as greatly embittered arise in him and are often the basis of a permanent estrangement. We have already mentioned that the child's sexual researches, with all their consequences, usually follow from this vital experience of his. As these brothers and sisters grow up, the boy's attitude to them undergoes very significant transformations. He may take his sister as a love-object by way of substitute for his faithless mother. Where there are several brothers, all of them courting a younger sister, situations of hostile rivalry, which are so important for later life, arise already in the nursery. A little girl may find in her elder brother a substitute for her father who no longer takes an affectionate interest in her as he did in her earliest years. Or she may take a younger sister as a substitute for the baby she has vainly wished for from her father.

This and very much else of a similar nature will be shown to you by the direct observation of children and by the consideration of clearly retained memories from childhood uninfluenced by analysis. From this you will conclude among other things that the position of a child in the family order is a factor of extreme importance in determining the shape of his later life and should deserve consideration in every life-history. But, what is more important, in view of this information which can be so easily obtained, you will not be able to recall without a smile the pronouncements of science in explanation of the prohibition of incest. There is no end to what has been invented on the subject. It has been said that sexual inclination is diverted from members of the same family who are of the opposite sex by the fact of having lived together from childhood; or, again, that a biological purpose of avoiding inbreeding is represented psychically by an innate horror of incest. In all this the fact is entirely overlooked that such an inexorable prohibition of it in law and custom would not be needed if there were any reliable natural barriers against the temptation to incest. The truth is just the opposite. A human being's first choice of an object is regularly an incestuous one, aimed, in the case of the male, at his mother and sister; and it calls for the severest prohibitions to deter this persistent infantile tendency from realization. Among the primitive races still living to-day, among savages, the prohibitions against incest are even very much stricter than among ourselves, and Theodor Reik has only recently shown in a brilliant work that the puberty rites of savages, which represent a re-birth, have the sense of releasing the boy from his incestuous bond with his mother and of reconciling him with his father.

Mythology will teach you that incest, which is supposed to be so much detested by humans, is unhesitatingly allowed to the gods. And you may learn from ancient history that incestuous sister marriage was a sanctified injunction upon the person of the Ruler (among the Egyptian Pharaohs and the Incas of Peru). What was in question was thus a privilege forbidden to the common herd.

Mother-incest was one of the crimes of Oedipus, parricide was the other. It may be remarked in passing that they are also the two great crimes proscribed by totemism, the first socio-religious institution of mankind.

But let us now turn from the direct observation of children to the analytic examination of adults who have become neurotic. What help does analysis give towards a further knowledge of the Oedipus complex? That can be answered in a word. Analysis confirms all that the legend describes. It shows that each of these neurotics has himself been an Oedipus or, what comes to the same thing, has, as a reaction to the complex, become a Hamlet. The analytic account of the Oedipus complex is, of course, a magnification and coarsening of the infantile sketch. The hatred of the father, the death-wishes against him, are no longer hinted at timidly, the affection for the mother admits that its aim is to possess her as a woman. Should we really attribute such blatant and extreme emotional impulses to the tender years of childhood, or is analysis deceiving us by an admixture of some new factor? It is not hard to find one. Whenever someone gives an account of a past event, even if he is a historian, we must take into account what he unintentionally puts back into the past from the present or from some intermediate time, thus falsifying his picture of it. In the case of a neurotic it is even a question whether this putting back is an entirely unintentional one; later on we shall have to discover reasons for this and have to do justice in general to the fact of 'retrospective phantasying'. We can easily see, too, that hatred of the father is reinforced by a number of factors arising from later times and circumstances and that the sexual desires towards the mother are cast into forms which must have been alien as yet to a child. But it would be a vain effort to seek to explain the whole Oedipus complex by retrospective phantasying and to attach it to later times. Its infantile core and more or less of its accessories remain as they were confirmed by the direct observation of children.

The clinical fact which meets us behind the form of the Oedipus complex as it is established by analysis is of the highest practical significance. We learn that at puberty, when the sexual instinct first makes its demands in full strength, the old familiar incestuous objects are taken up again and freshly cathected with libido. The infantile object-choice was only a feeble one, but it was a prelude, pointing the direction for the object-choice at puberty. At this point, then, very intense emotional processes come into play, following the direction of the Oedipus complex or reacting against it, processes which, however, since their premisses have become intolerable, must to a large extent remain apart from consciousness. From this time onwards, the human individual has to devote himself to the great task of detaching himself from his parents, and not until that task is achieved can he cease to be a child and become a member of the social community. For the son this task consists in detaching his libidinal wishes from his mother and employing them for the choice of a real outside love-object, and in reconciling himself with his father if he has remained in opposition to him, or in freeing himself from his pressure if, as a reaction to his infantile rebelliousness, he has become subservient to him. These tasks are set to everyone; and it is remarkable how seldom they are dealt with in an ideal manner - that is, in one which is correct both psychologically and socially. By neurotics, however, no solution at all is arrived at: the son remains all his life bowed beneath his father's authority and he is unable to transfer his libido to an outside sexual object. With the relationship changed round, the same fate can await the daughter. In this sense the Oedipus complex may justly be regarded as the nucleus of the neuroses.

As you may imagine, Gentlemen, I have passed very cursorily over a great number of considerations of both practical and theoretical importance connected with the Oedipus complex. Nor shall I enter into its variations or its possible reversal. Among its remoter connections I will only give you a further hint that it has turned out to have a highly important effect on literary production. In a valuable work Otto Rank has shown that dramatists of every period have chosen their material in the main from the Oedipus and incest complex and its variations and disguises. Nor should it be allowed to pass unnoticed that the two criminal wishes of the Oedipus complex were recognized as the true representatives of the uninhibited life of the instincts long before the time of psycho-analysis. Among the writings of the Encyclopaedist Diderot you will find a celebrated dialogue, *Le neveu Rameau*, which was rendered into German by no less a person than Goethe. There you may read this remarkable sentence: 'Si le petit sauvage était abandonné à lui-même, qu'il conservât toute son imbécillité, et qu'il réunît au peu de raison de l'enfant au berceau la violence des passions de l'homme de trente ans, il tordrait le col à son père et coucherait avec sa mère.'¹

But there is something else that I cannot pass by. The reminder of dreams given to us by the mother and wife of Oedipus must not be allowed to remain fruitless. Do you recall the out come of our dream-analyses - how the wishes that construct dreams are so often of a perverse or incestuous nature or reveal an unsuspected hostility to those who are nearest and dearest to the dreamer? At that time we gave no explanation of the origin of these evil impulses. Now you can find it for yourselves. They are allocations of the libido and object-cathexes which date from early infancy and have long since been abandoned as far as conscious life is concerned, but which prove still to be present at night-time and to be capable of functioning in a certain sense. Since, however, everyone, and not only neurotics, experiences these perverse, incestuous and murderous dreams, we may conclude that people who are normal to-day have passed along a path of development that has led through the perversions and object-cathexes of the Oedipus complex, that that is the path of normal development and that neurotics merely exhibit to us in a magnified and coarsened form what the analysis of dreams reveals to us in healthy people as well. And this is one of the reasons why I dealt with the study of dreams before that of neurotic symptoms.

¹ [If the little savage were left to himself, preserving all his foolishness and adding to the small sense of a child in the cradle the violent passions of a man of thirty, he would strangle his father and lie with his mother.]

LECTURE XXII

SOME THOUGHTS ON DEVELOPMENT AND REGRESSION - AETIOLOGY

LADIES AND GENTLEMEN, - You have heard that the libidinal function goes through a lengthy development before it can, in what is described as the normal manner, be enlisted in the service of reproduction. I should now like to bring to your attention the significance of this fact in the causation of the neuroses.

We are, I think, in agreement with the theories of general pathology in assuming that a development of this kind involves two dangers - first, of *inhibition*, and secondly, of *regression*. That is to say, in view of the general tendency of biological processes to variation, it is bound to be the case that not every preparatory phase will be passed through with equal success and completely superseded: portions of the function will be permanently held back at these early stages, and the total picture of development will be qualified by some amount of developmental inhibition.

Let us look for some analogies to these processes in other fields of knowledge. When, as often happened at early periods of human history, a whole people left their place of domicile and sought a new one, we may be certain that the whole of them did not arrive at the new location. Apart from other losses, it must regularly have happened that small groups or bands of the migrants halted on the way and settled at these stopping places while the main body went further. Or, as you know, to turn to a nearer comparison, in the highest mammals the male sex-glands, which are originally situated deep in the abdominal cavity, start upon a migration at a particular stage of intra-uterine life, which brings them almost directly under the skin of the pelvic extremity. As a consequence of this migration, we find in a number of male individuals that one of these paired organs has remained behind in the pelvic cavity, or that it has become permanently lodged in what is known as the inguinal canal, through which both organs must pass in the course of their migration, or at least that this canal has remained open, though it should normally close up after the sex-glands have completed their change of situation. Or again, when as a young student I was engaged under von Brücke's direction on my first piece of scientific work, I was concerned with the origin of the posterior nerve-roots in the spinal cord of a small fish of very archaic structure; I found that the nerve-fibres of these roots have their origin in large cells in the posterior horn of the grey matter, which is no longer the case in other vertebrates. But I also discovered soon afterwards that nerve-cells of this kind are present outside the grey matter the whole way to what is known as the spinal ganglion of the posterior root; and from this I inferred that the cells of these masses of ganglia had migrated from the spinal cord along the roots of the nerves. This is also shown by their evolutionary history. But in this small fish the whole path of their migration was demonstrated by the cells that had remained behind.

If you go into the matter more closely, you will have no difficulty in detecting the weak points in these comparisons. I will therefore declare without more ado that I regard it as possible in the case of every particular sexual trend that some portions of it have stayed behind at earlier stages of its development, even though other portions may have reached their final goal. You will recognize here that we are picturing every such trend as a current which has been continuous since the beginning of life but which we have divided up, to some extent artificially, into separate successive advances. Your impression that these ideas stand in need of greater clarification is justified; but to attempt it would take us too far afield. Let me further make it clear that we propose to describe the lagging behind of a part trend at an earlier stage as a *fixation* - a fixation, that is, of the instinct.

The second danger in a development by stages of this sort lies in the fact that the portions which have proceeded further may also easily return retrogressively to one of these earlier stages - what we describe as a *regression*. The trend will find itself led into a regression of this kind if the exercise of its function - that is, the attainment of its aim of satisfaction - is met, in its later or more highly developed form, by powerful external obstacles. It is plausible to suppose that fixation and regression are not independent of each other. The stronger the fixations on its path of development, the more readily will the function evade external difficulties by regressing to the fixations - the more incapable, therefore, does the developed function turn out to be of resisting external obstacles in its course. Consider that, if a people which is in movement has left strong detachments behind at the stopping-places on its migration, it is likely that the more advanced parties will be inclined to retreat to these stopping-places if they have been defeated or have come up against a superior enemy. But they will also be in the greater danger of being defeated the more of their number they have left behind on their migration.

It is important for your understanding of the neuroses that you should not leave this relation between fixation and regression out of sight. This will give you a firmer footing in facing the question of how the neuroses are caused - the question of the aetiology of the neuroses which we shall shortly have to meet.

For the moment we will dwell a little longer on regression. After what you have learnt of the development of the libidinal function, you will be prepared to hear that there are regressions of two sorts: a return to the objects first cathected by the libido, which, as we know, are of an incestuous nature, and a return of the sexual organization as a whole to earlier stages. Both sorts are found in the transference neuroses and play a great part in their mechanism. In particular, a return to the first incestuous objects of the libido is a feature that is found in neurotics with positively fatiguing regularity. There is much more to be said about regressions of the libido itself when we take into account as well another group of neuroses, the narcissistic ones, which for the time being we do not intend to do. These disorders give us access to other developmental processes of the libidinal function which we have not yet mentioned, and show us correspondingly new sorts of regression as well. But above all I think I ought to warn you now not to confuse *regression* with *repression* and help you to form a clear idea of the relations between the two processes. Repression, as you will recall, is the process by which an act which is admissible to consciousness, one, therefore, which belongs to the system *Pcs.*, is made unconscious - is pushed back, therefore, into the system *Ucs.* And we equally speak of repression if the unconscious mental act is altogether forbidden access to the neighbouring preconscious system and is turned back at the threshold by the censorship. Thus the concept of repression involves no relation to sexuality: I must ask you to take special note of that. It indicates a purely psychological process, which we can characterize still better if we call it a 'topographical' one. By this we intend to say that it is concerned with the psychical regions which we have assumed to exist, or, if we drop this clumsy working hypothesis, with the construction of the mental apparatus out of distinct psychical systems.

The comparison we have proposed has drawn our attention for the first time to the fact that we have not hitherto been using the word 'regression' in its general sense but in a quite special one. If we give it its general sense - of a return from a higher to a lower stage of development - then repression too can be subsumed under the concept of regression, for it too can be described as a return to an earlier and deeper stage in the development of a psychical act. In the case of repression, however, this retrogressive movement does not concern us, since we also speak of repression, in the *dynamic* sense, when a psychical act is held back at the lower, unconscious, stage. The fact is that repression is a topographico-dynamic concept, while regression is a purely descriptive one. What we have hitherto spoken of as regression, however, and have related to fixation, has meant exclusively a return of the libido to earlier stopping places in its development - something, that is, entirely different in its nature from repression and entirely independent of it. Nor can we call regression of the libido a purely psychical process and we cannot tell where we should localize it in the mental apparatus. And though it is true that it exercises the most powerful influence on mental life, yet the most prominent factor in it is the organic one.

Discussions like this, Gentlemen, are bound to become some what arid. So let us turn to clinical material in order to find applications of it that will be a little more impressive. Hysteria and obsessional neurosis are, as you know, the two chief representatives of the group of transference neuroses. Now it is true that in hysteria there is a regression of the libido to the primary incestuous sexual objects and that this occurs quite regularly; but there is as good as no regression to an earlier stage of the sexual organization. To offset this, the chief part in the mechanism of hysteria is played by repression. If I might venture to complete what we already know for certain about this neurosis by making a construction, I might explain the position thus. The unification of the component instincts under the primacy of the genitals has been accomplished; but its results come up against the resistance of the preconscious system which is linked with consciousness. Thus the genital organization holds good for the unconscious, but not in the same way for the preconscious; and this rejection on the part of the preconscious brings about a picture which has certain resemblances to the state of things before genital primacy. But it is nevertheless something quite different.

Of the two kinds of regression of the libido, that to an earlier phase of the sexual organization is by far the more striking. Since this is absent in hysteria, and since our whole view of the neuroses is still far too much under the influence of the study of hysteria, which was chronologically the first, the significance of libidinal regression also became clear to us far later than that of repression. We must be prepared to find that our views will be subjected to still further extensions and revaluations when we are able to take into consideration not only hysteria and obsessional neurosis but also the other, narcissistic neuroses.

In obsessional neurosis, on the contrary, it is the regression of the libido to the preliminary stage of the sadistic-anal organization that is the most striking fact and the one which is decisive for what is manifested in symptoms. The love-impulse is obliged, when this has happened, to disguise itself as a sadistic impulse. The obsessional idea 'I should like to kill you', when it has been freed from certain additions which are not a matter of chance but are indispensable, means at bottom nothing other than 'I should like to enjoy you in love'. If you consider further that there has been a simultaneous regression in regard to the object, so that these impulses apply only to those who are nearest and dearest to the patient, you can form some idea of the horror which these obsessions arouse in him and at the same time of the alien appearance which they present to his conscious perception. But repression, too, plays a great part in the mechanism of these neuroses, though in a cursory introduction like ours this is not easily demonstrated. A regression of the libido without repression would never produce a neurosis but would lead to a perversion. From this you can see that repression is the process which is most peculiar to neuroses and is most characteristic of them. Perhaps I may have an opportunity later of telling you what we know of the mechanism of the perversions, and you will see that in their case too things are not so simple as we should be glad to make them out.

I think, Gentlemen, that you will best come to terms with what you have just been told about fixation and regression of the libido if you will regard it as a preparation for research into the aetiology of the neuroses. Hitherto I have only given you one piece of information about this: namely that people fall ill of a neurosis if they are deprived of the possibility of satisfying their libido - that they fall ill owing to 'frustration', as I put it - and that their symptoms are precisely a substitute for their frustrated satisfaction. This is not supposed to mean, of course, that every frustration of a libidinal satisfaction makes the person it affects neurotic, but merely that the factor of frustration could be discerned in every case of neurosis that has been examined. Thus the proposition is not convertible. No doubt, too, you will have understood that this assertion does not claim to reveal the whole secret of the aetiology of neuroses but is only bringing into prominence one important and indispensable determinant.

In further pursuing the discussion of this thesis, are we to consider the nature of the frustration or the peculiar character of those who are affected by it? It is extremely seldom, after all, that frustration is universal and absolute. In order to operate pathogenically it must no doubt affect the mode of satisfaction which alone the subject desires, of which alone he is capable. There are in general very many ways of tolerating deprivation of libidinal satisfaction without falling ill as a result. In the first place, we know people who are able to put up with a deprivation of this kind without being injured: they are not happy, they suffer from longing, but they do not fall ill. Next, we must bear in mind that the sexual instinctual impulses in particular are extraordinarily *plastic*, if I may so express it. One of them can take the place of another, one of them can take over another's intensity; if the satisfaction of one of them is frustrated by reality, the satisfaction of another can afford complete compensation. They are related to one another like a network of intercommunicating channels filled with a liquid; and this is so in spite of their being subject to the primacy of the genitals - a state of affairs that is not at all easily combined in a single picture. Further, the component instincts of sexuality, as well as the sexual current which is compounded from them, exhibit a large capacity for changing their object, for taking another in its place - and one, therefore, that is more easily attainable. This displaceability and readiness to accept a substitute must operate powerfully against the pathogenic effect of a frustration. Among these protective processes against falling ill owing to deprivation there is one which has gained special cultural significance. It consists in the sexual trend abandoning its aim of obtaining a component or a reproductive pleasure and taking on another which is related genetically to the abandoned one but is itself no longer sexual and must be described as social. We call this process 'sublimation', in accordance with the general estimate that places social aims higher than the sexual ones, which are at bottom self-interested. Sublimation is, incidentally, only a special case of the way in which sexual trends are attached to other, non-sexual ones. We shall have to discuss it again in another connection.

You may now have an impression that deprivation has been reduced to insignificance owing to all these methods of tolerating it. But no, it retains its pathogenic power. The counter-measures are on the whole insufficient. There is a limit to the amount of unsatisfied libido that human beings on the average can put up with. The plasticity or free mobility of the libido is by no means fully preserved in everyone, and sublimation is never able to deal with more than a certain fraction of libido, quite apart from the fact that many people are gifted with only a small amount of capacity to sublimate. The most important of these limitations is evidently that upon the mobility of the libido, since it makes a person's satisfaction depend on the attainment of only a very small number of aims and objects. You have only to recall that an imperfect development of the libido leaves behind it very fertile and perhaps, too, very numerous libidinal fixations to early phases of the organization and of the finding of objects, which are for the most part incapable of real satisfaction, and you will recognize in libidinal fixation the second powerful factor which combines with frustration as the cause of illness. You can declare, as a schematic abbreviation, that libidinal fixation represents the predisposing, internal factor in the aetiology of the neuroses, while frustration represents the accidental, external one.

I take the opportunity here of warning you against taking sides in a quite unnecessary dispute. In scientific matters people are very fond of selecting one portion of the truth, putting it in the place of the whole and of then disputing the rest, which is no less true, in favour of this one portion. In just this way a number of schools of opinion have already split off from the psycho-analytic movement, some of which recognize the egoistic instincts while disavowing the sexual ones, and others attribute importance to the influence of the real tasks of life while overlooking the individual's past - and others besides. Now here we have a similar occasion for pointing a contrast and starting a controversy. Are neuroses *exogenous* or *endogenous* illnesses? Are they the inevitable result of a particular constitution or the product of certain detrimental (traumatic) experiences in life? More particularly, are they brought about by fixation of the libido (and the other features of the sexual constitution) or by the pressure of frustration? This dilemma seems to me no more sensible on the whole than another that I might put to you: does a baby come about through being begotten by its father or conceived by its mother? Both determinants are equally indispensable, as you will justly reply. In the matter of the causation of the neuroses the relation, if not precisely the same, is very similar. As regards their causation, instances of neurotic illness fall into a series within which the two factors - sexual constitution and experience, or, if you prefer it, fixation of the libido and frustration - are represented in such a manner that if there is more of the one there is less of the other. At one end of the series are the extreme cases of which you could say with conviction: these people, in consequence of the singular development of their libido, would have fallen ill in any case, whatever they had experienced and however carefully their lives had been sheltered. At the other end there are the cases, as to which, on the contrary, you would have had to judge that they would certainly have escaped falling ill if their lives had not brought them into this or that situation. In the cases lying within the series a greater or lesser amount of predisposition in the sexual constitution is combined with a lesser or greater amount of detrimental experience in their lives. Their sexual constitution would not have led them into a neurosis if they had not had these experiences, and these experiences would not have had a traumatic effect on them if their libido had been otherwise disposed. In this series I can perhaps allow a certain preponderance in significance to the predisposing factors; but even that admission depends on how far you choose to extend the frontiers of neurotic illness.

I propose, Gentlemen, that we should name a series of this kind a 'complemental series', and I forewarn you that we shall have occasion to construct others of the same kind.

The tenacity with which the libido adheres to particular trends and objects - what may be described as the 'adhesiveness' of the libido - makes its appearance as an independent factor, varying from individual to individual, whose determinants are quite unknown to us, but whose significance for the aetiology of the neuroses we shall certainly no longer underestimate. We should not, on the other hand, over-estimate the intimacy of this connection. For a similar 'adhesiveness' of the libido occurs (for unknown reasons) under numerous conditions in normal people, and it is found as a determining factor in people who are in one sense the contrary of neurotics - in perverts. It was known even before the days of psycho-analysis (cf. Binet) that in the anamnesis of perverts a very early impression of an abnormal instinctual trend or choice of object was quite often found, to which the subject's libido remained attached all through his life. It is often impossible to say what it is that enabled this impression to exercise such an intense attraction on the libido. I will describe a case of this sort which I myself observed.

The subject was a man who is to-day quite indifferent to the genitals and other attractions of women, but who can be plunged into irresistible sexual excitement only by a foot of a particular form wearing a shoe. He can recall an event from his sixth year which was decisive for the fixation of his libido. He was sitting on a stool beside the governess who was to give him lessons in English. The governess, who was an elderly, dried-up, plain-looking spinster, with pale-blue eyes and a snub nose, had something wrong with her foot that day, and on that account kept it, wearing a velvet slipper, stretched out on a cushion. Her leg itself was most decently concealed. A thin, scraggy foot, like the one he had then seen belonging to his governess, thereupon became (after a timid attempt at normal sexual activity at puberty) his only sexual object; and the man was irresistibly attracted if a foot of this kind was associated with other features besides which recalled the type of the English governess. This fixation of his libido, however, made him, not into a neurotic, but into a pervert - what we call a foot-fetishist. You see, then, that although an excessive, and moreover premature, fixation of the libido is indispensable for the causation of neuroses, the area of its effects extends far beyond the field of the neuroses. This determinant, too, is as little decisive in itself as is the frustration which we have already talked about.

Thus the problem of the causation of the neuroses seems to grow more complicated. In fact, psycho-analytic investigation makes us acquainted with a fresh factor, which is not taken into account in our aetiological series and which we can recognize easiest in cases in which what has hitherto been a healthy condition is suddenly disturbed by an onset of neurotic illness. In such people we regularly find indications of a contention between wishful impulses or, as we are in the habit of saying, a psychical conflict. One part of the personality champions certain wishes while another part opposes them and fends them off. Without such a conflict there is no neurosis. There would not seem to be anything peculiar in this. Our mental life is, as you know, perpetually agitated by conflicts which we have to settle. No doubt, therefore, special conditions must be fulfilled if such a conflict is to become pathogenic. We must ask what these conditions are, between what mental powers these pathogenic conflicts are played out, and what the relation is between the conflict and the other causative factors.

I hope to be able to give you adequate replies to these questions, even though the replies may be reduced to schematic dimensions. The conflict is conjured up by frustration, as a result of which the libido, deprived of satisfaction, is driven to look for other objects and paths. The necessary precondition of the conflict is that these other paths and objects arouse displeasure in one part of the personality, so that a veto is imposed which makes the new method of satisfaction impossible as it stands. From this point the construction of symptoms pursues its course, which we shall follow later. The repudiated libidinal trends nevertheless succeed in getting their way by certain roundabout paths, though not, it is true, without taking the objection into account by submitting to some distortions and mitigations. The roundabout paths are those taken by the construction of symptoms; the symptoms are the fresh or substitute satisfaction which has become necessary owing to the fact of frustration.

The meaning of psychical conflict can be adequately expressed in another way by saying that for an *external* frustration to become pathogenic an *internal* frustration must be added to it. In that case, of course, the external and internal frustration relate to different paths and objects. The external frustration removes one possibility of satisfaction and the internal frustration seeks to exclude *another* possibility, about which the conflict then breaks out. I prefer this way of representing the matter because it has a secret content. For it hints at the probability that the internal impediments arose from real external obstacles during the prehistoric periods of human development.

But what are the powers from which the objection to the libidinal trend arises? What is the other party to the pathogenic conflict? These powers, to put it quite generally, are the non sexual instinctual forces. We class them together as the 'ego instincts'. The psycho-analysis of the transference-neuroses gives us no easy access to a further dissecting of them; at most we come to know them to some extent by the resistances which oppose analysis. The pathogenic conflict is thus one between the ego-instincts and the sexual instincts. In a whole number of cases, it looks as though there might also be a conflict between different purely sexual trends. But in essence that is the same thing; for, of the two sexual trends that are in conflict, one is always, as we might say, 'ego-syntonic', while the other provokes the ego's defence. It therefore still remains a conflict between the ego and sexuality.

Over and over again, Gentlemen, when psycho-analysis has claimed that some mental event is the product of the sexual instincts, it has been angrily pointed out to it by way of defence that human beings do not consist only of sexuality, that there are instincts and interests in mental life other than sexual ones, that it ought not to derive 'everything' from sexuality, and so on. Well, it is most gratifying for once in a way to find ourselves in agreement with our opponents. Psycho-analysis has never forgotten that there are instinctual forces as well which are not sexual. It was based on a sharp distinction between the sexual instincts and the ego-instincts, and, in spite of all objections, it has maintained not that the neuroses are derived from sexuality but that their origin is due to a conflict between the ego and sexuality. Nor has it any conceivable reason for disputing the existence or significance of the ego-instincts while it pursues the part played by the sexual instincts in illness and in ordinary life. It has simply been its fate to begin by concerning itself with the sexual instincts because the transference neuroses made them the most easily accessible to examination and because it was incumbent on it to study what other people had neglected.

Nor is it a fact that psycho-analysis has paid no attention whatever to the non-sexual part of the personality. It is precisely the distinction between the ego and sexuality which has enabled us to recognize with special clarity that the ego instincts pass through an important process of development a development which is neither completely independent of the libido nor without a counter-effect upon it. Nevertheless, we are far less well acquainted with the development of the ego than of the libido, since it is only the study of the narcissistic neuroses that promises to give us an insight into the structure of the ego. We already have before us, however, a notable attempt by Ferenczi to make a theoretical construction of the stages of development of the ego, and there are at least two points at which we have a solid basis for judging that development. It is not our belief that a person's libidinal interests are from the first in opposition to his self-preservative interests; on the contrary, the ego endeavours at every stage to remain in harmony with its sexual organization as it is at the time and to fit itself into it. The succession of the different phases of libidinal development probably follows a prescribed programme. But the possibility cannot be rejected that this course of events can be influenced by the ego, and we may expect equally to find a certain parallelism, a certain correspondence, between the developmental phases of the ego and the libido; indeed a disturbance of that correspondence might provide a pathogenic factor. We are now faced by the important consideration of how the ego behaves if its libido leaves a strong fixation behind at some point in its (the libido's) development. The ego may accept this and consequently become to that extent perverse or, what is the same thing, infantile. It may, however, adopt a non compliant attitude to the libido's settling down in this position, in which case the ego experiences a *repression* where the libido has experienced a *fixation*.

Thus we discover that the third factor in the aetiology of the neuroses, the *tendency to conflict*, is as much dependent on the development of the ego as on that of the libido. Our insight into the causation of the neuroses is thus made more complete. First there is the most general precondition - frustration; next, fixation of the libido which forces it into particular directions; and thirdly, the tendency to conflict, arising from the development of the ego, which rejects these libidinal impulses. The situation, then, is not so very confused and hard to penetrate as it probably seemed to you during the course of my remarks. It is true, however, that we shall find we have not yet finished with it. There is something new to be added and something already familiar to be further examined.

In order to demonstrate to you the influence which the development of the ego has upon the construction of conflicts and upon the causation of neuroses, I should like to put an example before you - one which, it is true, is a complete invention but which is nowhere divorced from probability. I shall describe it (on the basis of the title of one of Nestroy's farces) as 'In the Basement and on the First Floor'. The care taker of the house inhabits the basement and its landlord, a wealthy and respectable gentleman, the first floor. Both have children, and we may suppose that the landlord's little daughter is allowed to play, without any supervision, with the proletarian girl. It might very easily happen, then, that the children's games would take on a 'naughty' - that is to say, a sexual - character, that they would play at 'father and mother', that they would watch each other at their most private business and excite each other's genitals. The caretaker's girl, though only five or six years old, would have had an opportunity of observing a good deal of adult sexuality, and she might well play the part of seductress in all this. These experiences, even if they were not continued over a long period, would be enough to set certain sexual impulses to work in the two children; and, after their games together had ceased, these impulses would for several years - afterwards find expression in masturbation. So much for their experiences in common; the final outcome in the two children will be very different. The caretaker's daughter will continue her masturbation, perhaps, till her menstrual periods begin and she will then give it up with no difficulty. A few years later she will find a lover and perhaps have a baby. She will take up some occupation or other, possibly become a popular figure on the stage and end up as an aristocrat. Her career is more likely to be less brilliant, but in any case she will go through her life undamaged by the early exercise of her sexuality and free from neurosis. With the landlord's little girl things will be different. At an early stage and while she is still a child she will get an idea that she has done something wrong; after a short time, but perhaps only after a severe struggle, she will give up her masturbatory satisfaction, but she will nevertheless still have some sense of oppression about her. When in her later girlhood she is in a position to learn something of human sexual intercourse, she will turn away from it with unexplained disgust and prefer to remain in ignorance. And now she will probably be subject to a fresh emergence of an irresistible pressure to masturbate of which she will not dare to complain. During the years in which she should exercise a feminine attraction upon some man, a neurosis breaks out in her which cheats her of marriage and her hopes in life. If after this an analysis succeeds in gaining an insight into her neurosis, it will turn out that the well-brought-up, intelligent and high-minded girl has completely repressed her sexual impulses, but that these, unconscious to her, are still attached to her petty experiences with her childhood friend.

The difference between the lives of these two, in spite of their having had the same experience, rests on the fact that the ego of one of them underwent a development with which the other never met. Sexual activity seemed to the caretaker's daughter just as natural and harmless in later life as it had in childhood. The landlord's daughter came under the influence of education and accepted its demands. From the suggestions offered to it, her ego constructed ideals of feminine purity and abstinence which are incompatible with sexual activity; her intellectual education reduced her interest in the feminine part which she was destined to play. Owing to this higher moral and intellectual development of her ego she came into conflict with the demands of her sexuality.

I will dwell for a little to-day on yet another point in ego development, partly because I have some remoter aims in view, but also because what follows is precisely calculated to justify the sharp separation between the ego-instincts and the sexual instincts which we favour but which is not self-evident. In forming our judgement of the two courses of development both of the ego and of the libido - we must lay emphasis on a consideration which has not often hitherto been taken into account. For both of them are at bottom heritages, abbreviated recapitulations of the development which all mankind has passed through from its primaeval days over long periods of time. In the case of the development of the libido, this *phylogenetic* origin is, I venture to think, immediately obvious. Consider how in one class of animals the genital apparatus is brought into the closest relation to the mouth, while in another it cannot be distinguished from the excretory apparatus, and in yet others it is linked to the motor organs - all of which you will find attractively set out in W. Bölsche's valuable book. Among animals one can find, so to speak in petrified form, every species of perversion of the sexual organization. In the case of human beings, however, this phylogenetic point of view is partly veiled by the fact that what is at bottom inherited is nevertheless freshly acquired in the development of the individual, probably because the same conditions which originally necessitated its acquisition persist and continue to operate upon each individual. I should like to add that origin ally the operation of these conditions was creative but that it is now evocative. Besides this, there is no doubt that the prescribed course of development can be disturbed and altered in each individual by recent external influences. But we know the power which forced a development of this kind upon humanity and maintains its pressure in the same direction to-day. It is, once again, frustration by reality, or, if we are to give it its true, grand name, the pressure of vital needs - Necessity (*Ανάγκη*). She has been a strict educator and has made much out of us. The neurotics are among those of her children to whom her strictness has brought evil results; but that is a risk with all education. This appreciation of the necessities of life heed not, incidentally, weigh against the importance, of 'internal developmental trends', if such can be shown to be present.

Now it is a very noteworthy fact that the sexual instincts and the self-preservative instincts do not behave in the same way towards real necessity. The self-preservative instincts, and everything to do with them, are much easier to educate: they learn early to comply with necessity and to arrange their developments in accordance with the instructions of reality. This is intelligible, since they could not obtain the objects they need in any other way; and without those objects the individual would inevitably perish. The sexual instincts are harder to educate, for at first they have no need of an object. Since they are attached like parasites, as it were, to the other bodily functions, and find their satisfaction auto-erotically on the subject's own body, they are to begin with withdrawn from the educative influence of real necessity, and they retain this characteristic of being self-willed and inaccessible to influence (what we describe as being 'unreasonable') in most people in some respect all through their lives. Moreover, as a rule the educability of a youthful individual is at an end when his sexual needs arise in their full strength. Educators are aware of this and act accordingly; but the findings of psycho-analysis may perhaps also induce them to shift the main impact of education on to the earliest years of childhood, from infancy onwards. The little creature is often completed by the fourth or fifth year of life, and after that merely brings gradually to light what is already within him.

In order to appreciate the full significance of the difference which I have pointed out between the two groups of instincts, we shall have to go back a long way and introduce one of those considerations which deserve to be described as *economic*. This leads us to one of the most important, but unluckily also one of the most obscure, regions of psycho-analysis. We may ask whether in the operation of our mental apparatus a main purpose can be detected, and we may reply as a first approximation that that purpose is directed to obtaining pleasure. It seems as though our total mental activity is directed towards achieving pleasure and avoiding unpleasure - that it is automatically regulated by the *pleasure principle*. We should of all things like to know, then, what determines the generation of pleasure and unpleasure; but that is just what we are ignorant of. We can only venture to say this much: that pleasure is *in some way* connected with the diminution, reduction or extinction of the amounts of stimulus prevailing in the mental apparatus, and that similarly unpleasure is connected with their increase. An examination of the most intense pleasure which is accessible to human beings, the pleasure of accomplishing the sexual act, leaves little doubt on this point. Since in such processes related to pleasure it is a question of what happens to *quantities* of mental excitation or energy, we call considerations of this kind economic. It will be noticed that we can describe the tasks and achievements of the mental apparatus in another and more general way than by stressing the acquisition of pleasure. We can say that the mental apparatus serves the purpose of mastering and disposing of the amounts of stimulus and sums of excitation that impinge on it from outside and inside. It is immediately obvious that the sexual instincts, from beginning to end of their development, work towards obtaining pleasure; they retain their original function unaltered. The other instincts, the ego-instincts, have the same aim to start with. But under the influence of the instructress Necessity, they soon learn to replace the pleasure principle by a modification of it. For them the task of avoiding unpleasure turns out to be almost as important as that of obtaining pleasure. The ego discovers that it is inevitable for it to renounce immediate satisfaction, to postpone the obtaining of pleasure, to put up with a little unpleasure and to abandon certain sources of pleasure altogether. An ego thus educated has become 'reasonable'; it no longer lets itself be governed by the pleasure principle, but obeys the *reality principle*, which also at bottom seeks to obtain pleasure, but pleasure which is assured through taking account of reality, even though it is pleasure postponed and diminished.

The transition from the pleasure principle to the reality principle is one of the most important steps forward in the ego's development. We know already that it is only late and unwillingly that the sexual instincts join in this piece of development, and we shall hear later the consequences for human beings of the fact that their sexuality is content with such a loose connection with external reality. And now in conclusion one last remark on this subject. If man's ego has its process of development like the libido, you will not be surprised to hear that there are also 'regressions of the ego', and you will be anxious to know too what part may be played in neurotic illnesses by this return of the ego to earlier phases of its development.

LECTURE XXIII

THE PATHS TO THE FORMATION OF SYMPTOMS

LADIES AND GENTLEMEN, - For laymen the symptoms constitute the essence of a disease and its cure consists in the removal of the symptoms. Physicians attach importance to distinguishing the symptoms from the disease and declare that getting rid of the symptoms does not amount to curing the disease. But the only tangible thing left of the disease after the symptoms have been got rid of is the capacity to form new symptoms. For that reason we will for the moment adopt the layman's position and assume that to unravel the symptoms means the same thing as to understand the disease.

Symptoms - and of course we are dealing now with psychical (or psychogenic) symptoms and psychical illness - are acts detrimental, or at least useless, to the subject's life as a whole, often complained of by him as unwelcome and bringing unpleasure or suffering to him. The main damage they do resides in the mental expenditure which they themselves involve and in the further expenditure that becomes necessary for fighting against them. Where there is an extensive formation of symptoms, these two sorts of expenditure can result in an extraordinary impoverishment of the subject in regard to the mental energy available to him and so in paralysing him for all the important tasks of life. Since this outcome depends mainly on the *quantity* of the energy which is thus absorbed, you will easily see that 'being ill' is in its essence a practical concept. But if you take up a theoretical point of view and disregard this matter of quantity, you may quite well say that we are *all* ill - that is, neurotic - since the preconditions for the formation of symptoms can also be observed in normal people.

We already know that neurotic symptoms are the outcome of a conflict which arises over a new method of satisfying the libido. The two forces which have fallen out meet once again in the symptom and are reconciled, as it were, by the compromise of the symptom that has been constructed. It is for that reason, too, that the symptom is so resistant: it is supported from both sides. We also know that one of the two partners to the conflict is the unsatisfied libido which has been repulsed by reality and must now seek for other paths to its satisfaction. If reality remains relentless even though the libido is ready to take another object in place of the one that has been refused to it, then it will finally be compelled to take the path of regression and strive to find satisfaction either in one of the organizations which it has already outgrown or from one of the objects which it has earlier abandoned. The libido is lured into the path of regression by the fixation which it has left behind it at these points in its development.

The path to perversion branches off sharply from that to neurosis. If these regressions rouse no objection from the ego, no neurosis will come about either; and the libido will arrive at some real, even though no longer normal, satisfaction. But if the ego, which has under its control not only consciousness but also the approaches to motor innervation and accordingly to the realization of mental desires, does not agree with these regressions, conflict will follow. The libido is, as it were, cut off and must try to escape in some direction where, in accordance with the requirements of the pleasure principle, it can find a discharge for its cathexis of energy. It must withdraw from the ego. An escape of this kind is offered it by the fixations on the path of its development which it has now entered on regressively - fixations from which the ego had protected itself in the past by repressions. By cathecting these repressed positions as it flows backward, the libido has withdrawn from the ego and its laws, and has at the same time renounced all the education it has acquired under the ego's influence. It was docile so long as satisfaction beckoned to it; but under the double pressure of external and internal frustration it becomes refractory, and recalls earlier and better times. Such is the libido's fundamentally unchangeable character. The ideas to which it now transfers its energy as a cathexis belong to the system of the unconscious and are subject to the processes which are possible there, particularly to condensation and displacement. In this way conditions are established which completely resemble those in dream-construction. The dream proper, which has been completed in the unconscious and is the fulfilment of an unconscious wishful phantasy, is brought up against a portion of (pre)conscious activity which exercises the office of censorship and which, when it has been indemnified, permits the formation of the manifest dream as a compromise. In the same way, what represents the libido in the unconscious has to reckon with the power of the preconscious ego. The opposition which had been raised against it in the ego pursues it as an 'anticathexis' and compels it to choose a form of expression which can at the same time become an expression of the opposition itself. Thus the symptom emerges as a many-times-distorted derivative of the unconscious libidinal wish-fulfilment, an ingeniously chosen piece of ambiguity with two meanings in complete mutual contradiction. In this last respect, however, there is a distinction between the construction of a dream and of a symptom. For in dream-formation the preconscious purpose is merely concerned to preserve sleep, to allow nothing that would disturb it to make its way into consciousness; it does not insist upon calling out sharply 'No! on the contrary!' to the unconscious wishful impulse. It can afford to be more tolerant because the situation of someone sleeping is less perilous. The state of sleep in itself bars any outlet into reality.

You see, then, that the libido's escape under conditions of conflict is made possible by the presence of fixations. The regressive cathexis of these fixations leads to the circumvention of the repression and to a discharge (or satisfaction) of the libido, subject to the conditions of a compromise being observed. By the roundabout path *viâ* the unconscious and the old fixations, the libido finally succeeds in forcing its way through to real satisfaction - though to one which is extremely restricted and scarcely recognizable as such. Let me add two comments to this conclusion. First, I should like you to notice how closely here the libido and the unconscious on one side and the ego, consciousness and reality on the other are shown to be interlinked, although to begin with they did not belong together at all. And secondly, I must ask you to bear in mind that everything I have said about this and what is still to follow relates only to the formation of symptoms in the neurosis of hysteria.

Where, then, does the libido find the fixations which it requires in order to break through the repressions? In the activities and experiences of infantile sexuality, in the abandoned component trends, in the objects of childhood which have been given up. It is to them, accordingly, that the libido returns. The significance of this period of childhood is twofold: on the one hand, during it the instinctual trends which the child has inherited with his innate disposition first become manifest, and secondly, others of his instincts are for the first time awakened and made active by external impressions and accidental experiences. There is no doubt, I think, that we are justified in making this twofold division. The manifestation of the innate disposition is indeed not open to any critical doubts, but analytic experience actually compels us to assume that purely chance experiences in childhood are able to leave fixations of the libido behind them. Nor do I see any theoretical difficulty in this. Constitutional dispositions are also undoubtedly after-effects of experiences by ancestors in the past; they too were once acquired. Without such acquisition there would be no heredity. And is it conceivable that acquisition such as this, leading to inheritance, would come to an end precisely with the generation we are considering? The significance of infantile experiences should not be totally neglected, as people like doing, in comparison with the experiences of the subject's ancestors and of his own maturity; on the contrary, they call for particular consideration. They are all the more momentous because they occur in times of incomplete development and are for that very reason liable to have traumatic effects. The studies on developmental mechanics by Roux and others have shown that the prick of a needle into an embryonic germinal layer in the act of cell-division results in a severe disturbance of development. The same injury inflicted on a larval or fully grown animal would do no damage.

Thus fixation of the libido in the adult, which we introduced into the aetiological equation of neurosis as representing the constitutional factor, now falls, for our purposes, into two further parts: the inherited constitution and the disposition acquired in early childhood. As we all know, a diagram is certain of a sympathetic reception from students. So I will summarize the position diagrammatically:

Causation of neurosis = Disposition due to Fixation of Libido + Accidental Experience (Traumatic)

The hereditary sexual constitution presents us with a great variety of dispositions, according as one component instinct or another, alone or in combination with others, is inherited in particular strength. The sexual constitution forms once again, together with the factor of infantile experience, a 'complemental series' exactly similar to the one we first came to know between disposition and the accidental experience of the adult. In both of them we find the same extreme cases and the same relations between the two factors concerned. And here the question suggests itself of whether the most striking kinds of libidinal regressions - those to earlier stages of the sexual organization - may not be predominantly determined by the hereditary constitutional factor. But it is best to postpone answering this question till we have been able to take a wider range of forms of neurotic illness into account.

Let us dwell now on the fact that analytic research shows the libido of neurotics tied to their infantile sexual experiences. It thus lends these the appearance of an enormous importance for the life and illness of human beings. They retain this importance undiminished so far as the work of therapeutics is concerned. But if we turn away from that task we can nevertheless easily see that there is a danger here of a misunderstanding which might mislead us into basing our view of life too one-sidedly on the neurotic situation. We must after all subtract from the importance of infantile experiences the fact that the libido has returned to them *regressively*, after being driven out of its later positions. In that case the contrary conclusion becomes very tempting - that these libidinal experiences had no importance at all at the time they occurred but only acquired it regressively. You will recall that we have already considered a similar alternative in our discussion of the Oedipus complex.

Once again we shall not find it hard to reach a decision. The assertion that the libidinal cathexis (and therefore the pathogenic significance) of the infantile experiences has been largely intensified by the regression of the libido is undoubtedly correct, but it would lead to error if we were to regard it alone as decisive. Other considerations must be allowed weight as well.

In the first place observation shows, in a manner that excludes all doubt, that the infantile experiences have an importance of their own and give evidence of it already in childhood. Children too have their neuroses, in which the factor of displacement backwards in time is necessarily very much reduced or is even completely absent, since the onset of the illness follows the traumatic experiences immediately. The study of these infantile neuroses protects us from more than one dangerous misunderstanding of the neuroses of adults, just as the dreams of children gave the key to an understanding of adult dreams. Children's neuroses are very common, much commoner than is supposed. They are often overlooked, regarded as signs of a bad or naughty child, often, too, kept under by the nursery authorities; but they can always be easily recognized in retrospect. They usually appear in the form of *anxiety hysteria*. We shall learn on a later occasion what that means. If a neurosis breaks out in later life, analysis regularly reveals it as a direct continuation of the infantile illness which may have emerged as no more than a veiled hint. As I have said, however, there are cases in which these signs of neurosis in childhood proceed uninterruptedly into a lifelong illness. We have been able to analyse a few examples of these children's neuroses in childhood itself - when they were actually present; but far more often we have had to be content with someone who has fallen ill in adult life enabling us to obtain a deferred insight into his childhood neurosis. In such cases we must not fail to make certain corrections and take certain precautions.

In the second place, we must reflect that it would be inconceivable for the libido to regress so regularly to the period of childhood unless there were something there to exercise an attraction on it. The fixation which we have supposed to be present at particular points in the course of development can only have a meaning if we regard it as consisting in the retention of a certain quota of libidinal energy. And finally I may point out to you that between the intensity and pathogenic importance of infantile and of later experiences a complementary relationship exists similar to the series we have already discussed. There are cases in which the whole weight of causation falls on the sexual experiences of childhood, cases in which those impressions exert a definitely traumatic effect and call for no other support than can be afforded them by an average sexual constitution and the fact of its incomplete development. Alongside of these cases there are others in which the whole accent lies on the later conflicts and the emphasis we find in the analysis laid on the impressions of childhood appears entirely as the work of regression. Thus we have extremes of 'developmental inhibition' and 'regression' and between them every degree of co-operation between the two factors.

These facts have a certain interest from the point of view of education, which plans the prevention of neuroses by intervening at an early stage in children's sexual development. So long as one focuses attention principally on infantile sexual experiences, one must suppose that one has done everything for the prophylaxis of nervous illnesses by taking care that the child's development is delayed and that it is spared experiences of the sort. We already know, however, that the preconditions for the causation of neuroses are complex and cannot be influenced in general if we take account of only a single factor. Strict protection of the young loses value because it is powerless against the constitutional factor. Besides, it is more difficult to carry out than educationists imagine and it brings with it two fresh dangers which must not be underestimated: the fact that it may achieve too much - that it may encourage an excess of sexual repression, with damaging results, and the fact that it may send the child out into life without any defence against the onrush of sexual demands that is to be looked for at puberty. Thus it remains extremely doubtful how far prophylaxis in childhood can be carried with advantage and whether an altered attitude to the immediate situation may not offer a better angle of approach for the prevention of neuroses.

Let us now go back to the symptoms. They create a substitute, then, for the frustrated satisfaction by means of a regression of the libido to earlier times, with which a return to earlier stages of object-choice or of the organization is inseparably bound up. We discovered some time ago that neurotics are anchored somewhere in their past; we know now that it is at a period of their past in which their libido did not lack satisfaction, in which they were happy. They search about in the history of their life till they find a period of that sort, even if they have to go back as far as the time when they were infants in arms - as they remember it or as they imagine it from later hints. In some way the symptom repeats this early infantile kind of satisfaction, distorted by the censorship arising from the conflict, turned as a rule to a feeling of suffering, and mingled with elements from the precipitating cause of the illness. The kind of satisfaction which the symptom brings has much that is strange about it.

We may disregard the fact that it is unrecognizable to the subject, who, on the contrary, feels the alleged satisfaction as suffering and complains of it. This transformation is a function of the psychical conflict under pressure of which the symptom had to be formed. What was once a satisfaction to the subject is, indeed, bound to arouse his resistance or his disgust to-day. We are familiar with a trivial but instructive model of this change of mind. The same child who once eagerly sucked the milk from his mother's breast is likely a few years later to display a strong dislike to drinking milk, which his upbringing has difficulties in overcoming. This dislike increases to disgust if a skin forms on the milk or the drink containing it. We cannot exclude the possibility, perhaps, that the skin conjures up a memory of the mother's breast, once so ardently desired. Between the two situations, however, there lies the experience of weaning, with its traumatic effects.

It is something else besides that makes symptoms seem strange to us and incomprehensible as a means of libidinal satisfaction. They do not remind us in the very least of anything from which we are in the habit of normally expecting satisfaction. Usually they disregard objects and in so doing abandon their relation to external reality. We can see that this is a consequence of turning away from the reality principle and of returning to the pleasure principle. But it is also a return to a kind of extended auto-erotism, of the sort that offered the sexual instinct its first satisfactions. In place of a change in the external world these substitute a change in the subject's own body: they set an internal act in place of an external one, an adaptation in place of an action - once again, something that corresponds, phylogenetically, to a highly significant regression. We shall only understand this in connection with something new that we have still to learn from the analytic researches into the formation of symptoms. We must further remember that the same processes belonging to the unconscious play a part in the formation of symptoms as in the formation of dreams - namely, condensation and displacement. A symptom, like a dream, represents something as fulfilled: a satisfaction in the infantile manner. But by means of extreme condensation that satisfaction can be compressed into a single sensation or innervation, and by means of extreme displacement it can be restricted to one small detail of the entire libidinal complex. It is not to be wondered at if we, too, often have difficulty in recognizing in a symptom the libidinal satisfaction whose presence we suspect and which is invariably confirmed.

I have warned you that we still have something new to learn; it is indeed something surprising and perplexing. By means of analysis, as you know, starting from the symptoms, we arrive at a knowledge of the infantile experiences to which the libido is fixated and out of which the symptoms are made. Well, the surprise lies in the fact that these scenes from infancy are not always true. Indeed, they are not true in the majority of cases, and in a few of them they are the direct opposite of the historical truth. As you will see, this discovery is calculated more than any other to discredit either analysis, which has led to this result, or the patients, on whose statements the analysis and our whole understanding of the neuroses are founded. But there is something else remarkably perplexing about it. If the infantile experiences brought to light by analysis were invariably real, we should feel that we were standing on firm ground; if they were regularly falsified and revealed as inventions, as phantasies of the patient, we should be obliged to abandon this shaky ground and look for salvation elsewhere. But neither of these things is the case: the position can be shown to be that the childhood experiences constructed or remembered in analysis are sometimes indisputably false and sometimes equally certainly correct, and in most cases compounded of truth and falsehood. Sometimes, then, symptoms represent events which really took place and to which we may attribute an influence on the fixation of the libido, and sometimes they represent phantasies of the patient's which are not, of course, suited to playing an aetiological role. It is difficult to find one's way about in this. We can make a first start, perhaps, with a similar discovery - namely, that the isolated childhood memories that people have possessed consciously from time immemorial and before there was any such thing as analysis may equally be falsified or at least may combine truth and falsehood in plenty. In their case there is seldom any difficulty in showing their incorrectness; so we at least have the reassurance of knowing that the responsibility for this unexpected disappointment lies, not with analysis, but in some way with the patients.

After a little reflection we shall easily understand what it is about this state of things that perplexes us so much. It is the low valuation of reality, the neglect of the distinction between it and phantasy. We are tempted to feel offended at the patient's having taken up our time with invented stories. Reality seems to us something worlds apart from invention, and we set a very different value on it. Moreover the patient, too, looks at things in this light in his normal thinking. When he brings up the material which leads from behind his symptoms to the wishful situations modelled on his infantile experiences, we are in doubt to begin with whether we are dealing with reality or phantasies. Later, we are enabled by certain indications to come to a decision and we are faced by the task of conveying it to the patient. This, however, invariably gives rise to difficulties. If we begin by telling him straight away that he is now engaged in bringing to light the phantasies with which he has disguised the history of his childhood just as every nation disguises its forgotten prehistory by constructing legends), we observe that his interest in pursuing the subject further suddenly diminishes in an undesirable fashion. He too wants to experience realities and despises everything that is merely 'imaginary'. If; however, we leave him, till this piece of work is finished, in the belief that we are occupied in investigating the real events of his childhood, we run the risk of his later on accusing us of being mistaken and laughing at us for our apparent credulity. It will be a long time before he can take in our proposal that we should equate phantasy and reality and not bother to begin with whether the childhood experiences under examination are the one or the other. Yet this is clearly the only correct attitude to adopt towards these mental productions. They too possess a reality of a sort. It remains a fact that the patient has created these phantasies for himself, and this fact is of scarcely less importance for his neurosis than if he had really experienced what the phantasies contain. The phantasies possess *psychical* as contrasted with *material* reality, and we gradually learn to understand that *in the world of the neuroses it is psychical reality which is the decisive kind*.

Among the occurrences which recur again and again in the youthful history of neurotics - which are scarcely ever absent - there are a few of particular importance, which also deserve, on that account, I think, to be brought into greater prominence than the rest. As specimens of this class I will enumerate these: observation of parental intercourse, seduction by an adult and threat of being castrated. It would be a mistake to suppose that they are never characterized by material reality; on the contrary, this is often established incontestably through enquiries from older members of the patient's family. It is by no means a rare thing, for instance, for a little boy, who is beginning to play with his penis in a naughty way and is not yet aware that one must conceal such activities, to be threatened by a parent or nurse with having his penis or his sinful hand cut off. Parents will often admit this when they are asked, since they think they have done something useful in making such a threat; a number of people have a correct conscious memory of such a threat, especially if it was made at a somewhat later period. If the threat is delivered by the mother or some other female she usually shifts its performance on to the father or the doctor. In *Struwwelpeter*, the famous work of the Frankfurt paediatrician Hoffmann (which owes its popularity precisely to an understanding of the sexual and other complexes of childhood), you will find castration softened into a cutting-off of the thumbs as a punishment for obstinate sucking. But it is highly improbable that children are threatened with castration as often as it appears in the analyses of neurotics. We shall be satisfied by realizing that the child puts a threat of this kind together in his imagination on the basis of hints, helped out by a knowledge that auto-erotic satisfaction is forbidden and under the impression of his discovery of the female genitals. Nor is it only in proletarian families that it is perfectly possible for a child, while he is not yet credited with possessing an understanding or a memory, to be a witness of the sexual act between his parents or other grown-up people; and the possibility cannot be rejected that he will be able to understand and react to the impression *in retrospect*. If, however, the intercourse is described with the most minute details, which would be difficult to observe, or if, as happens most frequently, it turns out to have been intercourse from behind *more ferarum* [in the manner of animals], there can be no remaining doubt that the phantasy is based on an observation of intercourse between animals (such as dogs) and that its motive was the child's unsatisfied scopophilia during puberty. The extreme achievement on these lines is a phantasy of observing parental intercourse while one is still an unborn baby in the womb. Phantasies of being seduced are of particular interest, because so often they are not phantasies but real memories. Fortunately, however, they are nevertheless not real as often as seemed at first to be shown by the findings of analysis. Seduction by an older child or by one of the same age is even more frequent than by an adult; and if in the case of girls who produce such an event in the story of their childhood their father figures fairly regularly as the seducer, there can be no doubt either of the imaginary nature of the accusation or of the motive that has led to it. A phantasy of being seduced when no seduction has occurred is usually employed by a child to screen the auto-erotic period of his sexual activity. He spares himself shame about masturbation by retrospectively phantasing a desired object into these earliest times. You must not suppose, however, that sexual abuse of a child by its nearest male relatives belongs entirely to the realm of phantasy. Most analysts will have treated cases in which such events were real and could be unimpeachably established; but even so they related to the later years of childhood and had been transposed into earlier times.

The only impression we gain is that these events of childhood are somehow demanded as a necessity, that they are among the essential elements of a neurosis. If they have occurred in reality, so much to the good; but if they have been withheld by reality, they are put together from hints and supplemented by phantasy. The outcome is the same, and up to the present we have not succeeded in pointing to any difference in the consequences, whether phantasy or reality has had the greater share in these events of childhood. Here we simply have once again one of the complementary relations that I have so often mentioned; moreover it is the strangest of all we have met with. Whence comes the need for these phantasies and the material for them? There can be no doubt that their sources lie in the instincts; but it has still to be explained why the same phantasies with the same content are created on every occasion. I am prepared with an answer which I know will seem daring to you. I believe these *primal phantasies*, as I should like to call them, and no doubt a few others as well, are a phylogenetic endowment. In them the individual reaches beyond his own experience into *primaeval* experience at points where his own experience has been too rudimentary. It seems to me quite possible that all the things that are told to us today in analysis as phantasy - the seduction of children, the inflaming of sexual excitement by observing parental intercourse, the threat of castration (or rather castration itself) - were once real occurrences in the *primaeval* times of the human family, and that children in their phantasies are simply filling in the gaps in individual truth with prehistoric truth. I have repeatedly been led to suspect that the psychology of the neuroses has stored up in it more of the antiquities of human development than any other source.

The things I have just been discussing, Gentlemen, compel me to enter more closely into the origin and significance of the mental activity which is described as 'phantasy'. As you are aware, it enjoys a universally high reputation, without its position in mental life having become clear. I have the following remarks to make about it. The human ego is, as you know, slowly educated by the pressure of external necessity to appreciate reality and obey the reality principle; in the course of this process it is obliged to renounce, temporarily or permanently, a variety of the objects and aims at which its striving for pleasure, and not only for sexual pleasure, is directed. But men have always found it hard to renounce pleasure; they cannot bring themselves to do it without some kind of compensation. They have therefore retained a mental activity in which all these abandoned sources of pleasure and methods of achieving pleasure are granted a further existence - a form of existence in which they are left free from the claims of reality and of what we call 'reality-testing'. Every desire takes before long the form of picturing its own fulfilment; there is no doubt that dwelling upon imaginary wish-fulfilments brings satisfaction with it, although it does not interfere with a knowledge that what is concerned is not real. Thus in the activity of phantasy human beings continue to enjoy the freedom from external compulsion which they have long since renounced in reality. They have contrived to alternate between remaining an animal of pleasure and being once more a creature of reason. Indeed, they cannot subsist on the scanty satisfaction which they can extort from reality. 'We cannot do without auxiliary constructions', as Theodor Fontane once said. The creation of the mental realm of phantasy finds a perfect parallel in the establishment of 'reservations' or 'nature reserves' in places where the requirements of agriculture, communications and industry threaten to bring about changes in the original face of the earth which will quickly make it unrecognizable. A nature reserve preserves its original state which everywhere else has to our regret been sacrificed to necessity. Everything, including what is useless and even what is noxious, can grow and proliferate there as it pleases. The mental realm of phantasy is just such a reservation withdrawn from the reality principle.

The best-known productions of phantasy are the so-called 'day-dreams', which we have already come across, imagined satisfactions of ambitious, megalomaniac, erotic wishes, which flourish all the more exuberantly the more reality counsels modesty and restraint. The essence of the happiness of phantasy - making the obtaining of pleasure free once more from the assent of reality - is shown in them unmistakably. We know that such day-dreams are the nucleus and prototype of night-dreams. A night-dream is at bottom nothing other than a day-dream that has been made utilizable owing to the liberation of the instinctual impulses at night, and that has been distorted by the form assumed by mental activity at night. We have already become familiar with the idea that even a day-dream is not necessarily conscious - that there are unconscious day-dreams, as well. Such unconscious day-dreams are thus the source not only of night-dreams but also of neurotic symptoms.

The importance of the part played by phantasy in the formation of symptoms will be made clear to you by what I have to tell you. I have explained how in the case of frustration the libido cathects regressively the positions which it has given up but to which some quotas of it have remained adhering. I shall not withdraw this or correct it, but I have to insert a connecting link. How does the libido find its way to these points of fixation? All the objects and trends which the libido has given up have not yet been given up in every sense. They or their derivatives are still retained with a certain intensity in phantasies. Thus the libido need only withdraw on to phantasies in order to find the path open to every repressed fixation. These phantasies have enjoyed a certain amount of toleration: they have not come into conflict with the ego, however sharp the contrasts between them may have been, so long as a particular condition is observed. This condition is of a *quantitative* nature and it is now upset by the backward flow of libido on to the phantasies. As a result of this surplus, the energetic cathexis of the phantasies is so much increased that they begin to raise claims, that they develop a pressure in the direction of becoming realized. But this makes a conflict between them and the ego inevitable. Whether they were previously preconscious or conscious, they are now subjected to repression from the direction of the ego and are at the mercy of attraction from the direction of the unconscious. From what are now unconscious phantasies the libido travels back to their origins in the unconscious - to its own points of fixation.

The libido's retreat to phantasy is an intermediate stage on the path to the formation of symptoms and it seem to call for a special name. C. G. Jung coined the very appropriate one of 'introversion', but then most inexpediently gave it another meaning as well. We will continue to take it that introversion denotes the turning away of the libido from the possibilities of real satisfaction and the hypercathexis of phantasies which have hitherto been tolerated as innocent. An introvert is not yet a neurotic, but he is in an unstable situation: he is sure to develop symptoms at the next shift of forces, unless he finds some other outlets for his dammed-up libido. The unreal character of neurotic satisfaction and the neglect of the distinction between phantasy and reality are on the other hand already determined by the fact of lingering at the stage of introversion.

You will no doubt have observed that in these last discussions I have introduced a fresh factor into the structure of the aetiological chain - namely the quantity, the magnitude, of the energies concerned. We have still to take this factor into account everywhere. A purely qualitative analysis of the aetiological determinants is not enough. Or, to put it another way, a merely *dynamic* view of these mental processes is insufficient; an *economic* line of approach is also needed. We must tell ourselves that the conflict between two trends does not break out till certain intensities of cathexis have been reached, even though the determinants for it have long been present so far as their subject-matter is concerned. In the same way, the pathogenic significance of the constitutional factors must be weighed according to how much *more* of one component instinct than of another is present in the inherited disposition. It may even be supposed that the disposition of all human beings is qualitatively alike and that they differ only owing to these quantitative conditions. The quantitative factor is no less decisive as regards capacity to resist neurotic illness. It is a matter of *what quota* of unemployed libido a person is able to hold in suspension and of *how large a fraction* of his libido he is able to divert from sexual to sublimated aims. The ultimate aim of mental activity, which may be described qualitatively as an endeavour to obtain pleasure and avoid unpleasure, emerges, looked at from the economic point of view, as the task of mastering the amounts of excitation (mass of stimuli) operating in the mental apparatus and of keeping down their accumulation which creates unpleasure.

This, then, is what I wanted to tell you about the formation of symptoms in the neuroses. But I must not fail to lay emphasis expressly once again on the fact that everything I have said here applies only to the formation of symptoms in hysteria. Even in obsessional neurosis there is much - apart from fundamentals, which remain unaltered - that will be found different. The anticathexes opposing the demands of the instincts (which we have already spoken of in the case of hysteria as well) become prominent in obsessional neurosis and dominate the clinical picture in the form of what are known as 'reaction formations'. We discover similar and even more far-reaching divergences in the other neuroses, where our researches into the mechanisms of symptom-formation are not yet concluded at any point.

Before I let you go to-day, however, I should like to direct your attention a little longer to a side of the life of phantasy which deserves the most general interest. For there is a path that leads back from phantasy to reality - the path, that is, of art. An artist is once more in rudiments an introvert, not far removed from neurosis. He is oppressed by excessively powerful instinctual needs. He desires to win honour, power, wealth, fame and the love of women; but he lacks the means for achieving these satisfactions. Consequently, like any other unsatisfied man, he turns away from reality and transfers all his interest, and his libido too, to the wishful constructions of his life of phantasy, whence the path might lead to neurosis. There must be, no doubt, a convergence of all kinds of things if this is not to be the complete outcome of his development; it is well known, indeed, how often artists in particular suffer from a partial inhibition of their efficiency owing to neurosis. Their constitution probably includes a strong capacity for sublimation and a certain degree of laxity in the repressions which are decisive for a conflict. An artist, however, finds a path back to reality in the following manner. To be sure, he is not the only one who leads a life of phantasy. Access to the half-way region of phantasy is permitted by the universal assent of mankind, and everyone suffering from privation expects to derive alleviation and consolation from it. But for those who are not artists the yield of pleasure to be derived from the sources of phantasy is very limited. The ruthlessness of their repressions force them to be content with such meagre day-dreams as are allowed to become conscious. A man who is a true artist has more at his disposal. In the first place, he understands how to work over his day-dreams in such a way as to make them lose what is too personal about them and repels strangers, and to make it possible for others to share in the enjoyment of them. He understands, too, how to tone them down so that they do not easily betray their origin from proscribed sources. Furthermore, he possesses the mysterious power of shaping some particular material until it has become a faithful image of his phantasy; and he knows, moreover, how to link so large a yield of pleasure to this representation of his unconscious phantasy that, for the time being at least, repressions are outweighed and lifted by it. If he is able to accomplish all this, he makes it possible for other people once more to derive consolation and alleviation from their own sources of pleasure in their unconscious which have become inaccessible to them; he earns their gratitude and admiration and he has thus achieved *through* his phantasy what originally he had achieved only *in* his phantasy - honour, power and the love of women.

LECTURE XXIV

THE COMMON NEUROTIC STATE

LADIES AND GENTLEMEN, - Now that we have disposed of such a difficult piece of work in our last discussions, I propose for a time to leave the subject and turn to you yourselves.

For I am aware that you are dissatisfied. You pictured an 'Introduction to Psycho-Analysis' very differently. What you expected to hear were lively examples, not the theory. On one occasion, you say, when I told you the parable of 'In the Basement and on the First Floor', you grasped something of the way in which neuroses are caused; the observations should have been real ones, however, and not made-up stories. Or when at the start I described two symptoms to you (not invented ones this time, let us hope) and described their solution and their relation to the patients' lives, the 'sense' of symptoms dawned on you. You hoped I should go on along those lines. But instead I gave you long-winded theories, hard to grasp, which were never complete but were always having something fresh added to them; I worked with concepts which I had not yet explained to you; I went from a descriptive account of things to a dynamic one and from that to what I called an 'economic' one; I made it hard for you to understand how many of the technical terms I used meant the same thing and were merely being interchanged for reasons of euphony; I brought up such far-reaching conceptions as those of the pleasure and reality principles and of phylogenetically inherited endowments; and, far from introducing you to anything, I paraded something before your eyes which constantly grew more and more remote from you.

Why did I not begin my introduction to the theory of neuroses with what you yourselves know of the neurotic state and what has long aroused your interest - with the peculiar characteristics of neurotic people, their incomprehensible reactions to human intercourse and external influences, their irritability, their incalculable and inexpedient behaviour? Why did I not lead you step by step from an understanding of the simpler, everyday forms of the neurotic state to the problems of its enigmatic, extreme manifestations?

Indeed, Gentlemen, I cannot even disagree with you. I am not so enamoured of my skill in exposition that I can declare each of its artistic faults to be a peculiar charm. I think myself that it might have been more to your advantage if I had proceeded otherwise; and that was, indeed, my intention. But one cannot always carry out one's reasonable intentions. There is often something in the material itself which takes charge of one and diverts one from one's first intentions. Even such a trivial achievement as the arrangement of a familiar piece of material is not entirely subject to an author's own choice; it takes what line it likes and all one can do is to ask oneself after the event why it has happened in this way and no other.

One reason is probably that the title 'Introduction to Psycho-Analysis' is no longer applicable to the present section, which is supposed to deal with the neuroses. An introduction to psycho-analysis is provided by the study of parapraxes and dreams; the theory of the neuroses is psycho-analysis itself. It would not, I believe have been possible to give you a knowledge of the subject-matter of the theory of the neuroses in so short a time except in this concentrated form. It was a question of presenting you with a connected account of the sense and significance of symptoms and of the external and internal determinants and mechanism of their formation. That is what I have tried to do; it is more or less the nucleus of what psycho-analysis has to teach to-day. It involved saying a great deal about the libido and its development and a little, too, about that of the ego. Our introduction had already prepared you in advance for the premisses of our technique and for the major considerations of the unconscious and of repression (of resistance). You will discover from one of the next lectures the points from which the work of psycho-analysis makes its further organic advance. For the time being I have made no secret of the fact that everything I have said is derived from the study of a single group of nervous disorders what are termed the 'transference neuroses'. Indeed, I have traced the mechanism of symptom-formation in the case only of the hysterical neurosis. Even if you have acquired no thorough knowledge and have not retained every detail, yet I hope that you have formed some picture of the methods by which psycho-analysis works, of the problems which it attacks and of the results at which it has arrived.

I have credited you with a wish that I might have started my description of the neuroses from the behaviour of neurotic people, from an account of the manner in which they suffer under their neurosis, of how they defend themselves against it and how they come to terms with it. No doubt that is an interesting topic, worth investigating; nor would it be very difficult to handle. But it would be of debatable wisdom to start with it. There would be a risk of not discovering the unconscious and at the same time of overlooking the great importance of the libido and of judging everything as it appears to the ego of the neurotic subject. It is obvious that this ego is not a trustworthy or impartial agency. The ego is indeed the power which disavows the unconscious and has degraded it into being repressed; so how can we trust it to be fair to the unconscious? The most prominent elements in what is thus repressed are the repudiated demands of sexuality, and it is quite self-evident that we should never be able to guess their extent and importance from the ego's conceptions. From the moment the notion of repression dawns on us, we are warned against making one of the two contesting parties (and the victorious one, at that) into being judge in the dispute. We are prepared to find that the ego's assertions will lead us astray. If we are to believe the ego, it was active at every point and itself willed and created its symptoms. But we know that it puts up with a good amount of passivity, which it afterwards tries to disguise and gloss over. It is true that it does not always venture on such an attempt; in the symptoms of obsessional neurosis it is obliged to admit that there is something alien which is confronting it and against which it can only defend itself with difficulty.

Anyone whom these warnings do not deter from taking the ego's counterfeits as sterling coin will have an easy time of it and will avoid all the resistances which oppose the psycho-analytic emphasis upon the unconscious, sexuality and the passivity of the ego. He will be able to declare like Alfred Adler that the 'neurotic character' is the cause of neuroses instead of their consequence; but neither will he be in a position to explain a single detail of symptom-formation or a single dream.

You will ask whether it may not be possible, however, to do justice to the part played by the ego in neurotic states and in the formation of symptoms without at the same time grossly neglecting the factors revealed by psycho-analysis. My reply is that that must certainly be possible and will sooner or later be done; but the road followed by the work of psycho-analysis does not admit of actually *beginning* with this. It is of course possible to foresee when psycho-analysis will be confronted by this task. There are neuroses in which the ego plays a far more intensive part than in those we have studied hitherto; we call them the 'narcissistic' neuroses. The investigation of these disorders will enable us to form an impartial and trustworthy judgement of the share taken by the ego in the onset of neuroses.

One of the ways in which the ego is related to its neuroses is, however, so obvious that it was possible to take it into account from the first. It seems never to be absent; but it is most clearly recognizable in a disorder which we are even to-day far from understanding - *traumatic neurosis*. For you must know that the same factors always come into operation in the causation and mechanism of every possible form of neurosis; but the chief importance in the construction of the symptoms falls now upon one and now upon another of these factors. The position is like that among the members of a theatrical company. Each of them is regularly cast for his own stock role - hero, confidant, villain, and so on; but each of them will choose a different piece for his benefit performance. In the same way phantasies which turn into symptoms are nowhere more obvious than in hysteria; the anticathexes or reaction-formations of the ego dominate the picture in obsessional neurosis; what in the case of dreams we have termed 'secondary revision' stands in the forefront in paranoia in the shape of delusions, and so on.

Thus in traumatic neuroses, and particularly in those brought about by the horrors of war, we are unmistakably presented with a self-interested motive on the part of the ego, seeking for protection and advantage - a motive which cannot, perhaps, create the illness by itself but which assents to it and maintains it when once it has come about. This motive tries to preserve the ego from the dangers the threat of which was the precipitating cause of the illness and it will not allow recovery to occur until a repetition of these dangers seems no longer possible or until compensation has been received for the danger that has been endured.

The ego takes a similar interest, however, in the development and maintenance of the neurosis in every other case. I have already shown that symptoms are supported by the ego, too, because they have a side with which they offer satisfaction to the repressing purpose of the ego. Moreover, settling the conflict by constructing a symptom is the most convenient way out and the one most agreeable to the pleasure principle: it unquestionably spares the ego a large amount of internal work which is felt as distressing. Indeed there are cases in which even the physician must admit that for a conflict to end in neurosis is the most harmless and socially tolerable solution. You must not be surprised to hear that even the physician may occasionally take the side of the illness he is combating. It is not his business to restrict himself in every situation in life to being a fanatic in favour of health. He knows that there is not only neurotic misery in the world but real, irremovable suffering as well, that necessity may even require a person to sacrifice his health; and he learns that a sacrifice of this kind made by a single person can prevent immeasurable unhappiness for many others. If we may say, then, that whenever a neurotic is faced by a conflict he takes flight into illness, yet we must allow that in some cases that flight is fully justified, and a physician who has recognized how the situation lies will silently and solicitously withdraw.

But let us disregard these exceptional cases and proceed with our discussion. In average circumstances we recognize that by escaping into a neurosis the ego obtains a certain internal 'gain from illness'. In some circumstances of life this is further accompanied by an appreciable *external* advantage bearing a greater or less real value. Consider the commonest example of this sort. A woman who is roughly treated and ruthlessly exploited by her husband will fairly regularly find a way out in neurosis, if her constitution makes it possible, if she is too cowardly or too moral to console herself secretly with another man, if she is not strong enough to separate from her husband in the face of every external deterrent, if she has no prospect of supporting herself or obtaining a better husband and if in addition she is still attached to this brutal husband by her sexual feelings. Her illness now becomes a weapon in her battle with her dominating husband - a weapon which she can use for her defence and misuse for her revenge. To complain of her illness is allowable, though to lament her marriage was probably not. She finds a helper in her doctor, she forces her usually inconsiderate husband to look after her, to spend money on her, to allow her at times to be away from home and so free from her married oppression. When an external or accidental gain from illness like this is really considerable and no real substitute for it is available, you must not reckon very high the chances of influencing the neurosis by your treatment.

You will now protest that what I have told you about the gain from illness argues entirely in favour of the view I have rejected - that the ego itself wills and creates the neurosis. Not too fast, Gentlemen! It may perhaps mean nothing more than that the ego puts up with the neurosis, which it cannot, after all, prevent, and that it makes the best of it, if anything can be made of it at all. That is only one side of the business, the pleasant side, it is true. So far as the neurosis has advantages the ego no doubt accepts it; but it does not only have advantages. As a rule it soon turns out that the ego has made a bad bargain by letting itself in for the neurosis. It has paid too dearly for an alleviation of the conflict, and the sufferings attached to the symptoms are perhaps an equivalent substitute for the torments of the conflict, but they probably involve an increase in unpleasure. The ego would like to free itself from this unpleasure of the symptoms without giving up the gain from illness, and this is just what it cannot achieve. This shows, then, that it was not so entirely active as it thought it was; and we shall bear this well in mind.

In your contact as doctors with neurotics, Gentlemen, you will soon give up expecting that the ones who raise the most lamentations and complaints about their illness will be the most eager to co-operate and will offer you the least resistance. It is rather the opposite. But of course you will easily realize that everything that contributes to the gain from illness will intensify the resistance due to repression and will increase the therapeutic difficulties. But to the portion of gain from illness which is, so to say, born with the illness we have to add another portion which arises later. When a psychical organization like an illness has lasted for some time, it behaves eventually like an independent organism; it manifests something like a self-preservative instinct; it establishes a kind of *modus vivendi* between itself and other parts of the mind, even with those which are at bottom hostile to it; and there can scarcely fail to be occasions when it proves once again useful and expedient and acquires, as it were, a *secondary function* which strengthens its stability afresh. Instead of an example from pathology, let us take a glaring instance from daily life. A capable working-man, who earns his living, is crippled by an accident in the course of his occupation. The injured man can no longer work, but eventually he obtains a small disablement pension, and he learns how to exploit his mutilation by begging. His new, though worsened, means of livelihood is based precisely on the very thing that deprived him of his former means of livelihood. If you could put an end to his injury you would make him, to begin with, without means of subsistence; the question would arise of whether he was still capable of taking up his earlier work again. What corresponds in the case of neuroses to a secondary exploitation like this of an illness may be described as the *secondary gain* from illness in contrast to the primary one.

In general, however, I should like to recommend that, while not under-estimating the *practical* importance of the gain from illness, you should not let yourselves be impressed by it theoretically. After all, apart from the exceptions recognized earlier, it always calls to mind the examples of 'animal intelligence' illustrated by Oberländer in *Fliegende Blätter*. An Arab was riding his camel along a narrow path cut in the steep face of a mountain. At a turn in the path he suddenly found himself face to face with a lion, which prepared to make a spring. He saw no way out: on one side a perpendicular cliff and on the other a precipice; retreat and flight were impossible. He gave himself up for lost. But the animal thought otherwise. He took one leap with his rider into the abyss - and the lion was left in the lurch. The help provided by a neurosis has as a rule no better success with the patient. This may be because dealing with a conflict by forming symptoms is after all an automatic process which cannot prove adequate to meeting the demands of life, and in which the subject has abandoned the use of his best and highest powers. If there were a choice, it would be preferable to go down in an honourable struggle with fate.

But I still owe you further enlightenment, Gentlemen, on my reasons for not starting my account of the theory of the neuroses with the common neurotic state. You may perhaps suppose that it was because in that case I should have had greater difficulty in proving the sexual causation of the neuroses. But you would be wrong there. In the case of the transference neuroses one must work one's way through the interpretation of symptoms before one can arrive at that discovery. In the common forms of what are known as the 'actual neuroses' the aetiological significance of sexual life is a crude fact that springs to the observer's eyes. I came upon it more than twenty years ago when one day I asked myself the question of why in the examination of neurotics their sexual activities were so regularly excluded from consideration. At that time I sacrificed my popularity with my patients for the sake of these enquiries; but after only a brief effort I was able to declare that 'if the *vita sexualis* is normal, there can be no neurosis' - and by this I meant no 'actual neurosis'. No doubt this statement passes too lightly over people's individual differences; it suffers, too, from the indefiniteness inseparable from the judgement of what is 'normal'. But as a rough guide it retains its value to this day. I had by then reached the point of establishing specific relations between particular forms of neurosis and particular sexual noxae; and I have no doubt that I could repeat the same observations to-day if similar pathological material were still at my disposal. I found often enough that a man who indulged in a certain kind of incomplete sexual satisfaction (for instance, manual masturbation) had fallen ill of a particular form of 'actual neurosis', and that this neurosis promptly gave place to another if he replaced this sexual *régime* by another equally far from being irreproachable. I was then in a position to infer the change in a patient's sexual mode of life from an alteration in his condition. I also learnt then to stand obstinately by my suspicions till I had overcome the patients' disingenuousness and compelled them to confirm my views. It is true that thereafter they preferred to go to other doctors who did not make such keen enquiries about their sexual life.

Even at that time I could not fail to notice that the causation of the illness did not always point to sexual life. One person, it was true, fell ill directly from a sexual noxa; but another did so because he had lost his fortune or had been through an exhausting organic illness. The explanation of these varieties came later, when we gained an insight into the suspected interrelations between the ego and the libido, and the explanation became the more satisfactory the deeper that insight extended. A person only falls ill of a neurosis if his ego has lost the capacity to allocate his libido in some way. The stronger is his ego, the easier will it be for it to carry out that task. Any weakening of his ego from whatever cause must have the same effect as an excessive increase in the claims of the libido and will thus make it possible for him to fall ill of a neurosis. There are other and more intimate relations between the ego and the libido; but these have not yet come within our scope, so I will not bring them up as part of my present explanation. What remains essential and makes things clear to us is that, in every case and no matter how the illness is set going, the symptoms of the neurosis are sustained by the libido and are consequently evidence that it is being employed abnormally.

Now, however, I must draw your attention to the decisive difference between the symptoms of the 'actual' neuroses and those of the psychoneuroses, the first group of which, the transference neuroses, have occupied us so much hitherto. In both cases the symptoms originate from the libido, and are thus abnormal employments of it, substitutive satisfactions. But the symptoms of the 'actual' neuroses - intracranial pressure, sensations of pain, a state of irritation in an organ, weakening or inhibition of a function - have no 'sense', no psychical meaning. They are not only manifested predominantly in the body (as are hysterical symptoms, for instance, as well), but they are also themselves entirely somatic processes, in the generating of which all the complicated mental mechanisms we have come to know are absent. Thus they really are what psychoneurotic symptoms were so long believed to be. But if so, how can they correspond to employments of the libido, which we have recognized as a force operating in the *mind*? Well, Gentlemen, that is a very simple matter. Let me remind you of one of the very first objections that were brought up against psycho-analysis. It was said then that it was occupied in finding a purely psychological theory of neurotic phenomena and this was quite hopeless, since psychological theories could never explain an illness. People had chosen to forget that the sexual function is not a purely psychical thing any more than it is a purely somatic one. It influences bodily and mental life alike. If in the symptoms of the psychoneuroses we have become acquainted with manifestations of disturbances in the *psychical* operation of the sexual function, we shall not be surprised to find in the 'actual' neuroses the direct *somatic* consequences of sexual disturbances.

Clinical medicine has given us a valuable pointer towards an interpretation of these disturbances, and one that has been taken into account by various enquirers. The 'actual' neuroses, in the details of their symptoms and also in their characteristic of influencing every organic system and every function, exhibit an unmistakable resemblance to the pathological states which arise from the chronic influence of external toxic substances and from a sudden withdrawal of them - to intoxications and conditions of abstinence. The two groups of disorders are brought together still more closely by intermediate conditions such as Grave's disease which we have learnt to recognize as equally due to the operation of toxic substances, but of toxins which are not introduced into the body from outside but originate in the subject's own metabolism. In view of these analogies, we cannot, I think, avoid regarding the neuroses as results of disturbances in the sexual metabolism, whether because more of these sexual toxins is produced than the subject can deal with, or whether because internal and even psychical conditions restrict the proper employment of these substances. The popular mind has from time immemorial paid homage to hypotheses of this kind on the nature of sexual desire, speaking of love as an 'intoxication' and believing that falling in love is brought about by love philtres - though here the operative agent is to some extent externalized. And for us this would be an occasion for recalling the erotogenic zones and our assertion that sexual excitation can be generated in the most various organs. But for the rest the phrase 'sexual metabolism' or 'chemistry of sexuality' is a term without content; we know nothing about it and cannot even decide whether we are to assume two sexual substances, which would then be named 'male' and 'female', or whether we could be satisfied with *one* sexual toxin which we should have to recognize as the vehicle of all the stimulant effects of the libido. The theoretical structure of psycho-analysis that we have created is in truth a superstructure, which will one day have to be set upon its organic foundation. But we are still ignorant of this.

What characterizes psycho-analysis as a science is not the material which it handles but the technique with which it works. It can be applied to the history of civilization, to the science of religion and to mythology, no less than to the theory of the neuroses, without doing violence to its essential nature. What it aims at and achieves is nothing other than the uncovering of what is unconscious in mental life. The problems of the 'actual' neuroses, whose symptoms are probably generated by direct toxic damage, offer psycho-analysis no points of attack. It can do little towards throwing light on them and must leave the task to biológico-medical research.

And now perhaps you understand better why I did not choose to arrange my material differently. If I had promised you an 'Introduction to the Theory of the Neuroses' the correct path would certainly have led from the simple forms of the 'actual' neuroses to the more complicated psychical illnesses due to disturbance of the libido. As regards the former I should have had to collect from various sources what we have learnt or believe we know, and in connection with the psychoneuroses psycho-analysis would have come up for discussion as the most important technical aid in throwing light on those conditions. But what I intended to give and what I announced was an 'Introduction to Psycho-Analysis'. It was more important for me that you should gain an idea of psycho-analysis than that you should obtain some pieces of knowledge about the neuroses; and for that reason the 'actual' neuroses, unproductive so far as psycho-analysis is concerned, could no longer have a place in the foreground. I believe, too, that I have made the better choice for you. For, on account of the profundity of its hypotheses and the comprehensiveness of its connections, psycho-analysis deserves a place in the interest of every educated person, while the theory of the neuroses is a chapter in medicine like any other.

Nevertheless you will rightly expect that we should devote some interest to the 'actual' neuroses as well. Their intimate clinical connection with the psychoneuroses would alone compel us to do so. I may inform you, then, that we distinguish three pure forms of 'actual' neuroses: neurasthenia, anxiety neurosis and hypochondria. Even this assertion is not uncontradicted. All the names are in use, it is true, but their content is indefinite and fluctuating. There are even doctors who oppose any dividing lines in the chaotic world of neurotic phenomena, any segregation of clinical entities or individual diseases, and who do not even recognize the distinction between the 'actual' neuroses and the psychoneuroses. I think they are going too far and have not chosen the path which leads to progress. The forms of neurosis which I have mentioned occur occasionally in their pure form; more often, however, they are intermixed with each other and with a psychoneurotic disorder. This need not lead us to abandon the distinction between them. Consider the difference between the study of minerals and of rocks in mineralogy. The minerals are described as individuals, no doubt on the basis of the fact that they often occur as crystals, sharply separated from their environment. Rocks consist of aggregations of minerals, which, we may be sure, have not come together by chance but as a result of what determined their origin. In the theory of the neuroses we still know too little of the course of their development to produce anything resembling petrology. But we are certainly doing the right thing if we start by isolating from the mass the individual clinical entities which we recognize and which are comparable to the minerals.

A noteworthy relation between the symptoms of the 'actual' neuroses and of the psychoneuroses makes a further important contribution to our knowledge of the formation of symptoms in the latter. For a symptom of an 'actual' neurosis is often the nucleus and first stage of a psychoneurotic symptom. A relation of this kind can be most clearly observed between neurasthenia and the transference neurosis known as 'conversion hysteria', between anxiety neurosis and anxiety hysteria, but also between hypochondria and the forms of disorder which will be mentioned later under the name of paraphrenia (dementia praecox and paranoia). Let us take as an example a case of hysterical headache or lumbar pain. Analysis shows us that, by condensation and displacement, it has become a substitutive satisfaction for a whole number of libidinal phantasies or memories. But this pain was also at one time a real one and it was then a direct sexual-toxic symptom, the somatic expression of a libidinal excitation. We are far from asserting that *all* hysterical symptoms contain a nucleus of this kind. But it remains a fact that this is especially often the case and that whatever somatic influences (whether normal or pathological) are brought about by libidinal excitation are preferred for the construction of hysterical symptoms. In such cases they play the part of the grain of sand which a mollusc coats with layers of mother-of-pearl. In the same way, the passing indications of sexual excitement which accompany the sexual act are employed by the psychoneurosis as the most convenient and appropriate material for the construction of symptoms.

A similar course of events affords peculiar diagnostic and therapeutic interest. It not at all infrequently happens in the case of a person who is disposed to a neurosis without actually suffering from a manifest one, that a pathological somatic change (through inflammation or injury perhaps) sets the activity of symptom-formation going; so that this activity hastily turns the symptom which has been presented to it by reality into the representative of all the unconscious phantasies which have only been lying in wait to seize hold of some means of expression. In such a case the physician will adopt sometimes one and sometimes another line of treatment. He will either endeavour to remove the organic basis, without bothering about its noisy neurotic elaboration; or he will attack the neurosis which has taken this favourable opportunity for arising and will pay little attention to its organic precipitating cause. The outcome will prove the one or the other line of approach right or wrong; it is impossible to make general recommendations to meet such mixed cases.

LECTURE XXV

ANXIETY

LADIES AND GENTLEMEN, - What I said to you in my last lecture about the general neurotic state will no doubt have struck you as the most incomplete and inadequate of all my pronouncements. I know that is true, and nothing will have surprised you more, I expect, than that there was nothing in it about anxiety, of which most neurotics complain, which they themselves describe as their worst suffering and which does in fact attain enormous intensity in them and may result in their adopting the craziest measures. But there at least I had no intention of giving you short measure. On the contrary, it was my intention to attack the problem of anxiety in neurotics particularly keenly and to discuss it at length with you.

I have no need to introduce anxiety itself to you. Every one of us has experienced that sensation, or, to speak more correctly, that affective state, at one time or other on our own account. But I think the question has never been seriously enough raised of why neurotics in particular suffer from anxiety so much more and so much more strongly than other people. Perhaps it has been regarded as something self-evident: the words '*nervös*' and '*ängstlich*' are commonly used interchangeably, as though they meant the same thing. But we have no right to do so: there are '*ängstlich*' people who are otherwise not at all '*nervös*' and, moreover, '*nervös*' people who suffer from many symptoms, among which a tendency to '*Angst*' is not included.

However that may be, there is no question that the problem of anxiety is a nodal point at which the most various and important questions converge, a riddle whose solution would be found to throw a flood of light on our whole mental existence. I will not assert that I can give you this complete solution; but you will certainly expect psycho-analysis to approach this subject too in quite a different way from academic medicine. Interest there seems mainly to be centred on tracing the anatomical paths along which the state of anxiety is brought about. We are told that the medulla oblongata is stimulated, and the patient learns that he is suffering from a neurosis of the vagus nerve. The medulla oblongata is a very serious and lovely object. I remember quite clearly how much time and trouble I devoted to its study many years ago. To-day, however, I must remark that I know nothing that could be of less interest to me for the psychological understanding of anxiety than knowledge of the path of the nerves along which its excitations pass.

It is possible at the start to work upon the subject of anxiety for quite a time without thinking at all of neurotic states. You will understand me at once when I describe this kind of anxiety as 'realistic' anxiety in contrast to 'neurotic' anxiety. Realistic anxiety strikes us as something very rational and intelligible. We may say of it that it is a reaction to the perception of an external danger - that is, of an injury which is expected and foreseen. It is connected with the flight reflex and it may be regarded as a manifestation of the self-preservative instinct. On what occasions anxiety appears - that is to say, in the face of what objects and in what situations - will of course depend to a large extent on the state of a person's knowledge and on his sense of power *vis-à-vis* the external world. We can quite understand how a savage is afraid of a cannon and frightened by an eclipse of the sun, while a white man, who knows how to handle the instrument and can foretell the eclipse, remains without anxiety in these circumstances. On other occasions it is actually superior knowledge that promotes anxiety, because it makes an early recognition of the danger possible. Thus the savage will be terrified at a trail in the jungle that tells an uninformed person nothing, because it warns him of the proximity of a wild animal; and an experienced sailor will look with terror at a small cloud in the sky that seems trivial to a passenger, because it tells him of an approaching hurricane.

On further consideration we must tell ourselves that our judgement that realistic anxiety is rational and expedient calls for drastic revision. For the only expedient behaviour when a danger threatens would be a cool estimate of one's own strength in comparison with the magnitude of the threat and, on the basis of that, a decision as to whether flight or defence, or possibly even attack, offers the best prospect of a successful issue. But in this situation there is no place at all for anxiety; everything that happens would be achieved just as well and probably better if no anxiety were generated. And you can see, indeed, that if the anxiety is excessively great it proves in the highest degree inexpedient; it paralyses all action, including even flight. Usually the reaction to danger consists in a mixture of the affect of anxiety and defensive action. A terrified animal is afraid and flees; but the expedient part of this is the 'flight' and not the 'being afraid'.

Thus one feels tempted to assert that the generation of anxiety is never an expedient thing. It may perhaps help us to see more clearly if we dissect the situation of anxiety more carefully. The first thing about it is *preparedness* for the danger, which manifests itself in increased sensory attention and motor tension. This expectant preparedness can be unhesitatingly recognized as an advantage; indeed, its absence may be made responsible for serious consequences. From it there then proceeds on the one hand motor action - flight in the first instance and at a higher level active defence - and on the other hand what we feel as a state of anxiety. The more the generation of anxiety is limited to a mere abortive beginning - to a signal - the more will the preparedness for anxiety transform itself without disturbance into action and the more expedient will be the shape taken by the whole course of events. Accordingly, the *preparedness* for anxiety seems to me to be the expedient element in what we call anxiety, and the *generation* of anxiety the inexpedient one.

I shall avoid going more closely into the question of whether our linguistic usage means the same thing or something clearly different by '*Angst* [anxiety]', '*Furcht* [fear]' and '*Schreck* [fright]'. I will only say that I think '*Angst*' relates to the state and disregards the object, while '*Furcht*' draws attention precisely to the object. It seems that '*Schreck*', on the other hand, does have a special sense; it lays emphasis, that is, on the effect produced by a danger which is not met by any preparedness for anxiety. We might say, therefore, that a person protects himself from fright by anxiety.

A certain ambiguity and indefiniteness in the use of the word '*Angst*' will not have escaped you. By 'anxiety' we usually understand the subjective state into which we are put by perceiving the 'generation of anxiety' and we call this an affect. And what is an affect in the dynamic sense? It is in any case something highly composite. An affect includes in the first place particular motor innervations or discharges and secondly certain feelings; the latter are of two kinds - perceptions of the motor actions that have occurred and the direct feelings of pleasure and unpleasure which, as we say, give the affect its keynote. But I do not think that with this enumeration we have arrived at the essence of an affect. We seem to see deeper in the case of some affects and to recognize that the core which holds the combination we have described together is the repetition of some particular significant experience. This experience could only be a very early impression of a very general nature, placed in the prehistory not of the individual but of the species. To make myself more intelligible - an affective state would be constructed in the same way as a hysterical attack; and, like it, would be the precipitate of a reminiscence. A hysterical attack may thus be likened to a freshly constructed individual affect, and a normal affect to the expression of a general hysteria which has become a heritage.

Do not suppose that the things I have said to you here about affects are the recognized stock-in-trade of normal psychology. They are on the contrary views that have grown up on the soil of psycho-analysis and are native only to it. What you may gather about affects from psychology - the James-Lange theory, for example - is quite beyond understanding or discussion to us psycho-analysts. But we do not regard our knowledge about affects as very assured either; it is a first attempt at finding our bearings in this obscure region. I will proceed, however. We believe that in the case of the affect of anxiety we know what the early impression is which it repeats. We believe that it is in the *act of birth* that there comes about the combination of unpleasurable feelings, impulses of discharge and bodily sensations which has become the prototype of the effects of a mortal danger and has ever since been repeated by us as the state of anxiety. The immense increase of stimulation owing to the interruption of the renovation of the blood (internal respiration) was at the time the cause of the experience of anxiety; the first anxiety was thus a toxic one. The name '*Angst* - '*angustiae*', '*Enge*'¹ - emphasizes the characteristic of restriction in breathing which was then present as a consequence of the real situation and is now almost invariably reinstated in the affect. We shall also recognize it as highly relevant that this first state of anxiety arose out of separation from the mother. It is, of course, our conviction that the disposition to repeat the first state of anxiety has been so thoroughly incorporated into the organism through a countless series of generations that a single individual cannot escape the affect of anxiety even if, like the legendary Macduff, he 'was from his mother's womb untimely ripped' and has therefore not himself experienced the act of birth. We cannot say what has become the prototype of the state of anxiety in the case of creatures other than mammals. And in the same way we do not know either what complex of feelings is in such creatures the equivalent to our anxiety.

It may perhaps interest you to learn how anyone could have formed such an idea as that the act of birth is the source and prototype of the affect of anxiety. Speculation had a very small share in it; what I did, rather, was to borrow from the *naïve* popular mind. Long years ago, while I was sitting with a number of other young hospital doctors at our mid-day meal in an inn, a house physician from the midwifery department told us of a comic thing that had happened at the last examination for midwives. A candidate was asked what it meant if meconium (excreta) made its appearance at birth in the water coming away, and she promptly replied: 'it means the child's frightened.' She was laughed at and failed in the examination. But silently I took her side and began to suspect that this poor woman from the humbler classes had laid an unerring finger on an important correlation.

¹ [These Latin and German words, meaning 'narrow place', 'straits', are from the same root as 'angst' (and 'anxiety').]

If we now pass over to consider neurotic anxiety, what fresh forms and situations are manifested by anxiety? There is much to be described here. In the first place we find a general apprehensiveness, a kind of freely floating anxiety which is ready to attach itself to any idea that is in any way suitable, which influences judgement, selects what is to be expected, and lies in wait for any opportunity that will allow it to justify itself. We call this state 'expectant anxiety' or 'anxious expectation'. People who are tormented by this kind of anxiety always foresee the most frightful of all possibilities, interpret every chance event as a premonition of evil and exploit every uncertainty in a bad sense. A tendency to an expectation of evil of this sort is to be found as a character trait in many people whom one cannot otherwise regard as sick; one calls them over-anxious or pessimistic. A striking amount of expectant anxiety, however, forms a regular feature of a nervous disorder to which I have given the name of 'anxiety neurosis' and which I include among the 'actual' neuroses.

A second form of anxiety, in contrast to the ones I have just described, is bound psychically and attached particular objects or situations. This is the anxiety of the extremely multifarious and often very strange 'phobias'. Stanley Hall, the respected American psychologist, has recently taken the trouble to present us with a whole series of these phobias in all the magnificence of Greek names. This sounds like a list of the ten Plagues of Egypt, though their number goes far beyond ten. Listen to all the things that can become the object or content of a phobia: darkness, open air, open spaces, cats, spiders, caterpillars, snakes, mice, thunderstorms, sharp points, blood, enclosed spaces, crowds, solitude, crossing bridges, sea voyages and railway journeys, etc., etc. A first attempt at finding one's way about in this confusion suggests a division into three groups. Some of the dreaded objects and situations have something uncanny about them for normal people as well, some relation to danger; and such phobias, therefore, do not strike us as unintelligible, though their strength is greatly exaggerated. Thus most of us have a sense of repulsion if we meet with a snake. Snake phobia, we might say, is a universal human characteristic; and Darwin has described most impressively how he could not avoid feeling fear of a snake that struck at him, even though he knew that he was protected from it by a thick sheet of glass. We may refer to a second group the cases in which a relation to a danger is still present, though we are accustomed to minimize the danger and not to anticipate it. The majority of situation phobias belong to this group. We know that there is more chance of an accident when we are on a railway-journey than when we stay at home - the chance of a collision; we know, too, that a ship may go down, in which case there is a probability of being drowned; but we do not think about these dangers, and travel by rail and ship without anxiety. It cannot be disputed that we should fall into the river if the bridge collapsed at the moment we were crossing it; but that happens so exceedingly seldom that it does not arise as a danger. Solitude, too, has its dangers and in certain circumstances we avoid it; but there is no question of our not being able to tolerate it under any condition even for a moment. Much the same is true of crowds, of enclosed spaces, of thunderstorms and so on. What in general appears to us strange in these phobias of neurotics is not so much their content as their intensity. The anxiety of phobias is positively overwhelming. And sometimes we get an impression that what neurotics are afraid of are not at all the same things and situations which may in certain circumstances cause anxiety in us too and which they describe by the same names.

We are left with a third group of phobias, which is quite beyond our comprehension. When a strong, grown-up man is unable owing to anxiety to walk along a street or cross a square in his own familiar home-town, when a healthy, well-developed woman is thrown into insensate anxiety because a cat has brushed against the edge of her dress or because a mouse has run across the room, how are we to relate these things to the danger which they obviously constitute for the phobic subject? In the case of such animal phobias there can be no question of an exaggeration of universal human antipathies, since, as though to demonstrate the contrary, there are numerous people who cannot pass by a cat without coaxing it and stroking it. The mouse that these women are so much afraid of is also [in German] one of the chief terms of affection; a girl who is delighted when her lover calls her one will often scream with terror when she sees the pretty creature which bears that name. In the case of the man with agoraphobia the only explanation that we can reach is that he is behaving like a small child. A child is actually taught as part of his education to avoid such situations as dangerous; and our agoraphobic will in fact be saved from his anxiety if we accompany him across the square.

The two forms of anxiety that I have just described - the freely floating expectant anxiety and the sort which is bound to phobias - are independent of each other. One is not a higher stage, as it were, of the other; and they only appear simultaneously in exceptional cases and, so to speak, accidentally. The most powerful general apprehensiveness need not be expressed in phobias; people whose whole existence is restricted by agoraphobia may be entirely free from pessimistic expectant anxiety. Some phobias - for instance, agoraphobia and railway phobia - are demonstrably acquired at a fairly mature age, while others - such as fear of darkness, thunderstorms and animals - seem to have been present from the first. Those of the former kind have the significance of severe illnesses; the latter make their appearance rather as eccentricities or whims. If a person exhibits one of these latter, one may suspect as a rule that he will have other similar ones. I must add that we class all these phobias as *anxiety hysteria*; that is to say, we regard them as a disorder closely related to the familiar conversion hysteria.

The third of the forms of neurotic anxiety faces us with the puzzling fact that here the connection between anxiety and a threatening danger is completely lost to view. For instance, anxiety may appear in hysteria as an accompaniment to hysterical symptoms, or in some chance condition of excitement in which, it is true, we should expect some manifestation of affect but least of all one of anxiety; or it may make its appearance, divorced from any determinants and equally incomprehensible to us and to the patient, as an unrelated attack of anxiety. Here there is no sign whatever of any danger or of any cause that could be exaggerated into one. We next learn from these spontaneous attacks that the complex which we describe as a state of anxiety is capable of fragmentation. The total attack can be represented by a single, intensely developed symptom, by a tremor, a vertigo, by palpitation of the heart, or by dyspnoea; and the general feeling by which we recognize anxiety may be absent or have become indistinct. Yet these conditions, which we describe as 'anxiety-equivalents', have to be equated with anxiety in all clinical and aetiological respects.

Two questions now arise. Can we relate neurotic anxiety, in which danger plays little or no part, to realistic anxiety, which is invariably a reaction to danger? And how are we to understand neurotic anxiety? We shall certainly be inclined in the first instance to hold fast to our expectation that where there is anxiety there must be something that one is afraid of.

Clinical observation affords us a number of hints towards understanding neurotic anxiety, and I will give you their tenor:-

(a) It is not difficult to establish the fact that expectant anxiety or general apprehensiveness is closely dependent on certain happenings in sexual life, or, let us say, certain employments of the libido. The simplest and most instructive case of this sort occurs in people who expose themselves to what is known as unconsummated excitation - that is, people in whom violent sexual excitations meet with no sufficient discharge, cannot be brought to a satisfying conclusion - men for instance, while they are engaged to be married, and women whose husbands are insufficiently potent or, as a precaution, perform the sexual act in an incomplete or curtailed fashion. In such circumstances the libidinal excitation vanishes and anxiety appears in its place whether in the form of expectant anxiety or in attacks and anxiety-equivalents. Interruption of the sexual act as a precaution, if it is practised as a sexual *régime*, is such a regular cause of anxiety neurosis in men, but more particularly in women, that in medical practice it is advisable in such cases to begin by investigating this aetiology. It will then be found on countless occasions that the anxiety neurosis disappears when the sexual abuse is discontinued.

The fact of there being a connection between sexual restraint and anxiety states is, so far as I know, no longer disputed even by physicians who have no contact with psycho-analysis. But I can well believe that an attempt is made to reverse the relation and to put forward the view that the people concerned are such as are already inclined to apprehensiveness and for that reason practise restraint in sexual matters as well. This, however, is decisively contradicted by the behaviour of women, whose sexual activity is essentially of a passive nature - is determined, that is to say, by their treatment by the man. The more passionate a woman is - the more inclined, therefore, to sexual intercourse and the more capable of being satisfied - the more certain she is to react with manifestations of anxiety to a man's impotence or to coitus interruptus, whereas in the case of anaesthetic women or those without much libido such ill-treatment plays a far smaller part.

Of course, the sexual abstinence now so warmly recommended by doctors only has the same importance in generating anxiety states when the libido which is prevented from finding a satisfying discharge is correspondingly strong and has not been dealt with for the greater part by sublimation. Indeed, the decision on whether the outcome is to be illness or not always lies with quantitative factors. Even where what is in question is not illness but the form assumed by a person's character, it is easy to recognize that sexual restriction goes hand in hand with some kind of anxiousness and hesitancy, while intrepidity and impudent daring bring along with them a free indulgence of sexual needs. However much these relations are altered and complicated by a variety of cultural influences, it nevertheless remains true of the average of mankind that anxiety has a close connection with sexual limitation.

I am far from having told you of all the observations that speak in favour of the genetic relation I have asserted to exist between libido and anxiety. Among them, for instance, is the influence on anxiety disorders of certain phases of life to which, as in the case of puberty and the time of the menopause, a considerable increase in the production of libido may be attributed. In some states of excitement, too, it is possible to observe directly a mixture of libido and anxiety and the final replacement of libido by anxiety. The impression one gains from all these facts is twofold: first, that what is in question is an accumulation of libido which is kept away from its normal employment, and secondly, that here we are entirely in the sphere of somatic processes. How anxiety arises from libido is not at first discernible; we can only recognize that libido is absent and that anxiety is observed in its place.

(b) A second pointer is to be found in the analysis of the psychoneuroses, and especially of hysteria. We have seen that in this illness anxiety often appears in company with the symptoms, but that unbound anxiety appears, too, manifested as an attack or as a chronic condition. The patients cannot say what it is they are afraid of, and, by the help of an unmistakable secondary revision, link it to the first phobias that come to hand - such as dying, going mad, or having a stroke. If the situation out of which the anxiety (or the symptoms accompanied by anxiety) arose is subjected to analysis, we can as a rule discover what normal course of psychical events has failed to occur and has been replaced by phenomena of anxiety. To express it in another way: we construct the unconscious process as it would have been if it had not experienced any repression and had proceeded unhindered into consciousness. This process would have been accompanied by a particular affect, and we now learn to our surprise that this affect accompanying the normal course of events is invariably replaced by anxiety after repression has occurred, no matter what its own quality may be. Thus, when we have a hysterical anxiety-state before us, its unconscious correlate may be an impulse of a similar character - anxiety, shame, embarrassment - or, just as easily, a positive libidinal excitation or a hostile aggressive one, such as rage or anger. Anxiety is therefore the universally current coinage for which any affective impulse is or can be exchanged if the ideational content attached to it is subjected to repression.

(c) We make a third discovery when we come to patients suffering from obsessional actions, who seem in a remarkable way exempt from anxiety. If we try to hinder their carrying out of their obsessional action - their washing or their ceremonial - or if they themselves venture upon an attempt to give up one of their compulsions, they are forced by the most terrible anxiety to yield to the compulsion. We can see that the anxiety was screened by the obsessional action, and that the latter was only performed in order to avoid the anxiety. In an obsessional neurosis, therefore, anxiety which would otherwise inevitably set in is replaced by the formation of a symptom, and if we turn to hysteria we find a similar relation: the result of the process of repression is either a generating of anxiety pure and simple, or anxiety accompanied by the formation of a symptom, or a more complete formation of a symptom without anxiety. It would thus seem not to be wrong in an abstract sense to assert that in general symptoms are only formed to escape an otherwise unavoidable generating of anxiety. If we adopt this view, anxiety is placed, as it were, in the very centre of our interest in the problems of neurosis.

Our observations on anxiety neurosis led us to conclude that the deflection of the libido from its normal employment, which causes the development of anxiety, takes place in the region of somatic processes. Analyses of hysteria and obsessional neurosis yield the additional conclusion that a similar deflection with the same outcome may also be the result of a refusal on the part of the *psychical* agencies. This much, therefore, we know about the origin of neurotic anxiety. It still sounds fairly indefinite; but for the moment I see no path that would lead us further. The second problem we set ourselves - of establishing a connection between neurotic anxiety, which is libido put to an abnormal employment, and realistic anxiety, which corresponds to a reaction to danger - seems even harder to solve. One might suppose that these were two quite disparate things; and yet we have no means of distinguishing in our feelings between realistic anxiety and neurotic anxiety.

We finally arrive at the connection we are in search of, if we take as our starting-point the opposition we have so often asserted between the ego and the libido. As we know, the generation of anxiety is the ego's reaction to danger and the signal for taking flight. If so, it seems plausible to suppose that in neurotic anxiety the ego is making a similar attempt at flight from the demand by its libido, that it is treating this internal danger as though it were an external one. This would therefore fulfil our expectation that where anxiety is shown there is something one is afraid of. But the analogy could be carried further. Just as the attempt at flight from an external danger is replaced by standing firm and the adoption of expedient measures of defence, so too the generation of neurotic anxiety gives place to the formation of symptoms, which results in the anxiety being bound.

The difficulty in understanding now lies else here. The anxiety which signifies a flight of the ego from its libido is after all supposed to be derived from that libido itself. This is obscure and it reminds us not to forget that after all a person's libido is fundamentally something of his and cannot be contrasted with him as something external. It is the topographical dynamics of the generation of anxiety which are still obscure to us - the question of what mental energies are produced in what process and from what mental systems they derive. This is once more a question which I cannot promise to answer: but there are two other tracks which we must not fail to follow and in doing so we shall once more be making use of direct observation and analytic enquiry as a help to our speculations. We will turn to the genesis of anxiety in children and to the source of the neurotic anxiety which is attached to phobias.

Apprehensiveness in children is something very usual, and it seems most difficult to distinguish whether it is neurotic or realistic anxiety. Indeed the value of making the distinction is put in question by the behaviour of children. For on the one hand we are not surprised if a child is frightened of all strangers, or of new situations and things; and we account for this reaction very easily as being due to his weakness and ignorance. Thus we attribute to children a strong inclination to realistic anxiety and we should regard it as quite an expedient arrangement if this apprehensiveness were an innate heritage in them. Children would merely be repeating in this the behaviour of prehistoric men and of modern primitive peoples who as a result of their ignorance and helplessness are afraid of every novelty and of many familiar things which no longer cause us any anxiety to-day. And it would fit in perfectly with our expectation if children's phobias, in part at least, were the same as those which we may attribute to the primaeval periods of human development.

On the other hand we cannot overlook the fact that not all children are anxious to the same degree, and that precisely children who exhibit a special timidity towards objects and in situations of every kind turn out later to be neurotic. Thus the neurotic disposition betrays itself also by an outspoken tendency to realistic anxiety; apprehensiveness appears to be the primary thing and we reach the conclusion that the reason why children and, later, growing youths and girls are afraid of the height of their libido is because in fact they are afraid of everything. The genesis of anxiety from libido would in this way be denied; and if one examined into the determinants of realistic anxiety, consistency would lead one to the view that consciousness of one's own weakness and helplessness - inferiority according to Adler's terminology, - if it can be prolonged from childhood into adult life, is the final basis of neuroses.

This sounds so simple and seductive that it has a claim on our attention. It is true that it would involve a displacement of the riddle of the neurotic state. The continued existence of the sense of inferiority - and thus, of what determine anxiety and the formation of symptoms - seems so well assured that what calls for an explanation is rather how, as an exception, what we know as health can come about. But what is revealed by a careful examination of apprehensiveness in children? At the very beginning, what children are afraid of is strange *people*; situations only become important because they include people, and impersonal things do not come into account at all until later. But a child is not afraid of these strangers because he attributes evil intentions to them and compares his weakness with their strength, and accordingly assesses them as dangers to his existence, safety and freedom from pain. A child who is mistrustful in this way and terrified of the aggressive instinct which dominates the world is a theoretical construction that has quite miscarried. A child is frightened of a strange face because he is adjusted to the sight of a familiar and beloved figure - ultimately of his mother. It is his disappointment and longing that are transformed into anxiety - his libido, in fact, which has become unemployable, which cannot at that time be held in suspense and is discharged as anxiety. And it can scarcely be a matter of chance, either, that in this situation which is the prototype of the anxiety of children there is a repetition of the determinant of the first state of anxiety during the act of birth - namely, separation from the mother.

In children the first phobias relating to situations are those of darkness and solitude. The former of these often persists throughout life; both are involved when a child feels the absence of some loved person who looks after it - its mother, that is to say. While I was in the next room, I heard a child who was afraid of the dark call out: 'Do speak to me, Auntie! I'm frightened!' 'Why, what good would that do? You can't see me.' To this the child replied: 'If someone speaks, it gets lighter.' Thus a *longing* felt in the dark is transformed into a *fear* of the dark. Far from its being the case that neurotic anxiety is only secondary and a special case of realistic anxiety, we see on the contrary that in a small child something that behaves like realistic anxiety shares its essential feature - origin from unemployed libido - with neurotic anxiety. Innately, children seem to have little true realistic anxiety. In all the situations which can later become determinants of phobias (on heights, on narrow bridges over water, on railway journeys, on ships) children exhibit no anxiety; and, to be sure, the greater their ignorance the less their anxiety. It would have been a very good thing if they had inherited more of such life-preserving instincts, for that would have greatly facilitated the task of watching over them to prevent their running into one danger after another. The fact is that children, to begin with, over-estimate their strength and behave fearlessly because they are ignorant of dangers. They will run along the brink of the water, climb on to the window-sill, play with sharp objects and with fire - in short, do everything that is bound to damage them and to worry those in charge of them. When in the end realistic anxiety is awakened in them, that is wholly the result of education; for they cannot be allowed to make the instructive experiences themselves.

If, then, there are children who come some way to meet this education in anxiety, and who go on to find dangers themselves that they have not been warned against, this is sufficiently explained by the fact that they have a greater amount of innate libidinal need in their constitution or have been prematurely spoiled by libidinal satisfaction. It is not to be wondered at if such children include, too, the later neurotics: as we know, what most facilitates the development of a neurosis is an incapacity to tolerate a considerable damming-up of libido over any great length of time. You will observe that here once more the constitutional factor comes into its rights - and these, indeed, we have never sought to dispute. We are only on our guard against those who in its favour neglect all other claims, and who introduce the constitutional factor at points at which the combined results of observation and analysis show that it does not belong or must take the last place.

Let me sum up what we have learnt from our observations of the apprehensiveness of children. Infantile anxiety has very little to do with realistic anxiety, but, on the other hand, is closely related to the neurotic anxiety of adults. Like the latter, it is derived from unemployed libido and it replaces the missing love-object by an external object or by a situation.

You will be glad to hear that the analysis of phobias has not much more that is new to teach us. For the same thing happens with them as with children's anxiety: unemployable libido is being constantly transformed into an apparently realistic anxiety and thus a tiny external danger is introduced to represent the claims of the libido. There is nothing to be wondered at in this agreement, for the infantile phobias are not only the prototype of the later ones which we class as 'anxiety hysteria' but are actually their precondition and the prelude to them. Every hysterical phobia goes back to an infantile anxiety and is a continuation of it, even if it has a different content and must thus be given another name. The difference between the two disorders lies in their mechanism. In order that libido shall be changed into anxiety, it no longer suffices in the case of adults for the libido to have become momentarily unemployable in the form of a longing. Adults have long since learnt how to hold such libido in suspense or to employ it in some other way. If, however, the libido belongs to a psychical impulse which has been subjected to repression, then circumstances are re-established similar to those in the case of a child in whom there is still no distinction between conscious and unconscious; and by mean of regression to the infantile phobia a passage is opened, as it were, through which the transformation of libido into anxiety can be comfortably accomplished.

As you will recall, we have dealt with repression at great length, but in doing so we have always followed the vicissitudes only of the idea that is to be repressed - naturally, since this was easier to recognize and describe. We have always left on one side the question of what happens to the affect that was attached to the repressed idea; and it is only now that we learn that the immediate vicissitude of that affect is to be transformed into anxiety, whatever quality it may have exhibited apart from this in the normal course of events. This transformation of affect is, however, by far the most important part of the process of repression. It is not so easy to speak of this, since we cannot assert the existence of unconscious affects in the same sense as that of unconscious ideas. An idea remains the same, except for the one difference, whether it is conscious or unconscious; we can state what it is that corresponds to an unconscious idea. But an affect is a process of discharge and must be judged quite differently from an idea; what corresponds to it in the unconscious cannot be declared without deeper reflection and a clarification of our hypotheses about psychical processes. And that we cannot undertake here. We will, however, emphasize the impression we have now gained that the generation of anxiety is intimately linked to the system of the unconscious.

I have said that transformation into anxiety - it would be better to say discharge in the form of anxiety - is the immediate vicissitude of libido which is subjected to repression. I must add that that vicissitude is not the only or the definitive one. In the neuroses processes are in action which endeavour to bind this generating of anxiety and which even succeed in doing so in various ways. In phobias, for instance, two phases of the neurotic process can be clearly distinguished. The first is concerned with repression and the changing of libido into anxiety, which is then bound to an external danger. The second consists in the erection of all the precautions and guarantees by means of which any contact can be avoided with this danger, treated as it is like an external thing. Repression corresponds to an attempt at flight by the ego from libido which is felt as a danger. A phobia may be compared to an entrenchment against an external danger which now represents the dreaded libido. The weakness of the defensive system in phobias lies, of course, in the fact that the fortress which has been so greatly strengthened towards the outside remains assailable from within. A projection outwards of the danger of libido can never succeed thoroughly. For that reason, in other neuroses other systems of defence are in use against the possible generation of anxiety. That is a most interesting part of the psychology of the neuroses; but unluckily it would lead us too far and it presupposes a deeper specialized knowledge. I will only add one thing more. I have already spoken to you of the 'anticathexis' which is employed by the ego in the process of repression and which must be permanently maintained in order that the repression may have stability. This anticathexis has the task of carrying through the various forms of defence against the generating of anxiety after repression.

Let us return to the phobias. I can safely say that you now see how inadequate it is merely to seek to explain their content, to take no interest in anything but how it comes about that this or that object or some particular situation or other has been made into the object of the phobia. The content of a phobia has just about as much importance in relation to it as the manifest façade of a dream has in relation to the dream. It must be admitted, subject to the necessary qualifications, that among the contents of phobias there are a number which, as Stanley Hall insists, are adapted to serve as objects of anxiety owing to phylogenetic inheritance. It tallies with this, indeed, that many of these anxiety-objects can only establish their connection with danger by a symbolic tie.

We thus find ourselves convinced that the problem of anxiety occupies a place in the question of the psychology of the neuroses which may rightly be described as central. We have received a strong impression of the way in which the generation of anxiety is linked to the vicissitudes of the libido and the system of the unconscious. There is only a single point that we have found disconnected - a gap in our views: the single, yet scarcely disputable, fact that realistic anxiety must be regarded as a manifestation of the ego's self-preservative instincts.

LECTURE XXVI

THE LIBIDO THEORY AND NARCISSISM

LADIES AND GENTLEMEN, - We have repeatedly (and only recently once again) had to deal with the distinction between the ego-instincts and the sexual instincts. In the first place, repression showed us that the two can come into opposition to each other, that the sexual instincts are then ostensibly subdued and are obliged to find satisfaction for themselves along regressive and roundabout paths, and that in doing so they are able to find compensation for their defeat in their indomitability. We next learnt that the two kinds of instincts are from the first differently related to Necessity the educator, so that their course of development is not the same and they do not enter into the same connection with the reality principle. Lastly, we seem to have found that the sexual instincts are linked by much closer bonds than the ego-instincts to the affective state of anxiety - a conclusion which seems incomplete in only one important respect. In order to establish it more firmly, therefore, I will bring forward the further noteworthy fact that if hunger and thirst (the two most elementary self-preservative instincts) are unsatisfied, the result is never their transformation into anxiety, whereas the changing of unsatisfied libido into anxiety is, as we have seen, among the best known and most frequently observed of phenomena.

Our right to separate the ego-instincts from the sexual ones cannot, no doubt, be shaken: it is implied in the existence of sexual life as a distinct activity of the individual. The only question is what importance we attribute to this separation, how deep-going we wish to consider it. The answer to this question, however, will be guided by how far we are able to establish the extent to which the sexual instincts behave differently in their somatic and mental manifestations from the others which we are contrasting with them, and how important the consequences are which arise from those differences. Moreover, we have, of course, no motive for asserting an essential difference between the two groups of instincts which is not plainly appreciable. Both of them come before us merely as designations of sources of energy in the individual, and the discussion as to whether they are fundamentally one or essentially different and as to when, if they are one, they became separate from each other - this discussion cannot be conducted on the basis of the connotation of the terms but must keep to the biological facts lying behind them. At the moment we know too little about these, and even if we knew more it would have no relevance for our analytic task.

It is obvious, too, that we shall profit very little if, following Jung's example, we insist upon the original unity of all the instincts and give the name of 'libido' to the energy manifested in all of them. Since no device whatever will make it possible to eliminate the sexual function from mental life, we shall in that case find ourselves obliged to speak of sexual and asexual libido. But the name of libido is properly reserved for the instinctual forces of sexual life, as has hitherto been our practice.

In my opinion, therefore, the question of how we are to carry the undoubtedly justifiable separation between the sexual and self-preserved instincts is not of much importance for psycho-analysis. Nor is psycho-analysis competent to answer the question. Biology, however, offers a number of suggestive possibilities which speak in favour of the distinction having some importance. Sexuality is, indeed, the single function of the living organism which extends beyond the individual and is concerned with his relation to the species. It is an unmistakable fact that it does not always, like the individual organism's other functions, bring it advantages, but, in return for an unusually high degree of pleasure, brings dangers which threaten the individual's life and often enough destroy it. It is probable, too, that quite special metabolic processes are necessary, differing from all others, in order to maintain a portion of the individual life as a disposition for its descendants. And finally, the individual organism, which regards itself as the main thing and its sexuality as a means, like any other, for its own satisfaction, is from the point of view of biology only an episode in a succession of generations, a short-lived appendage to a germ-plasm endowed with virtual immortality - like the temporary holder of an entail which will outlast him.

The psycho-analytic explanation of the neuroses does not, however, call for such far-ranging considerations. The separate following-up of the sexual and ego-instincts has helped us to find the key to an understanding of the group of transference neuroses. We have been able to trace them back to the basic situation in which the sexual instincts have come into a dispute with the self-preservative instincts, or, to put it in biological (though less precise) terms, a situation in which one aspect of the ego, as an independent individual organism, comes into conflict with its other aspect, as a member of a succession of generations. A dissension of this kind may perhaps only occur in human beings, and on that account neurosis may, generally speaking, constitute their prerogative over the animals. The excessive development of their libido and - what is perhaps made possible precisely by that - their development of a richly articulated mental life seem to have created the determinants for the occurrence of such a conflict. It is at once obvious that these are also the determinants for the great advances that human beings have made beyond what they have in common with the animals; so that their susceptibility to neurosis would only be the reverse side of their other endowments. But these too are only speculations, which are diverting us from our immediate task.

Hitherto it has been a premiss of our work that we can distinguish the ego-instincts from the sexual ones by their manifestations. With the transference neuroses this could be done without difficulty. We termed the cathexes of energy which the ego directs towards the objects of its sexual desires 'libido'; all the others, which are sent out by the self-preservative instincts, we termed 'interest'. By tracing the course of the libidinal cathexes, their transformations and final vicissitudes, we were able to obtain a first insight into the machinery of the mental forces. For this purpose the transference neuroses offered us the most favourable material. But the ego, its composition out of various organizations and their construction and mode of functioning, remained hidden from us; and we were driven to suspect that only the analysis of other neurotic disorders would be able to bring us the necessary insight.

We began at an early date to extend psycho-analytic observations to these other illnesses. Already in 1908 Karl Abraham, after an exchange of thoughts with me, pronounced the main characteristic of dementia praecox (which was reckoned among the psychoses) to be that *in it the libidinal cathexis of objects was lacking*. But the question then arose of what happened to the libido of dementia praecox patients which was turned away from objects. Abraham did not hesitate to give the answer: it is turned back on to the ego and *this reflexive turning-back is the source of the megalomania* in dementia praecox. Megalomania is in every way comparable to the familiar sexual overvaluation of the object in erotic life. In this way for the first time we learnt to understand a trait in a psychotic illness by relating it to normal erotic life.

I may tell you at once that these first explanations of Abraham's have been accepted in psycho-analysis and have become the basis of our attitude to the psychoses. We thus slowly became familiar with the notion that the libido, which we find attached to objects and which is the expression of an effort to obtain satisfaction in connection with those objects, can also leave the objects and set the subject's own ego in their place; and this notion was gradually built up more and more consistently. The name for this way of allocating the libido - 'narcissism' - was borrowed by us from a perversion described by Paul Näcke in which an adult treats his own body with all the caresses that are usually devoted to an outside sexual object.

Reflection will quickly suggest that if any such fixation of the libido to the subject's own body and personality, instead of to an object does occur, it cannot be an exception or a trivial event. On the contrary it is probable that this narcissism is the universal and original state of things, from which object-love is only later developed, without the narcissism necessarily disappearing on that account. Indeed we had to recall from the history of the development of object-libido that many sexual instincts begin by finding satisfaction in the subject's own body - *auto-erotically*, as we say - and that this capacity for auto-erotism is the basis of the lagging-behind of sexuality in the process of education in the reality principle. Auto-erotism would thus be the sexual activity of the narcissistic stage of allocation of the libido.

To put the matter shortly, we pictured the relation of ego libido to object-libido in a way which I can make plain to you by an analogy from zoology. Think of those simplest of living organisms which consist of a little-differentiated globule of protoplasmic substance. They put out protrusions, known as pseudopodia, into which they cause the substance of their body to flow over. They are able, however, to withdraw the protrusions once more and form themselves again into a globule. We compare the putting-out of these protrusions, then, to the emission of libido on to objects while the main mass of libido can remain in the ego; and we suppose that in normal circumstances ego-libido can be transformed unhindered into object-libido and that this can once more be taken back into the ego.

With the help of these ideas we are now able to explain a whole number of mental states or, to express it more modestly, to describe them in terms of the libido theory - states which we must reckon as belonging to normal life, such as the psychical behaviour of a person in love, during an organic illness or when asleep. As regards the state of sleep, we assumed that it was based on turning-away from the external world and adopting a wish to sleep. The mental activity during the night which is manifested in dreams takes place, we found, in obedience to a wish to sleep and is moreover dominated by purely egoistic motives. We may now add, on the lines of the libido theory, that sleep is a state in which all object-cathexes, libidinal as well as egoistic, are given up and withdrawn into the ego. May not this throw a fresh light on the recuperating effect of sleep and on the nature of fatigue in general? The picture of the blissful isolation of intra-uterine life which a sleeper conjures up once more before us every night is in this way completed on its psychical side as well. In a sleeper the primal state of distribution of the libido is restored - total narcissism, in which libido and ego-interest, still united and indistinguishable, dwell in the self-sufficing ego.

This is the place for two remarks. First, how do we differentiate between the concepts of narcissism and egoism? Well, narcissism, I believe, is the libidinal complement to egoism. When we speak of egoism, we have in view only the individual's *advantage*; when we talk of narcissism we are also taking his libidinal satisfaction into account. As practical motives the two can be traced separately for quite a distance. It is possible to be absolutely egoistic and yet maintain powerful object-cathexes, in so far as libidinal satisfaction in relation to the object forms part of the ego's needs. In that case, egoism will see to it that striving for the object involves no damage to the ego. It is possible to be egoistic and at the same time to be excessively narcissistic - that is to say, to have very little need for an object, whether, once more, for the purpose of direct sexual satisfaction, or in connection with the higher aspirations, derived from sexual need, which we are occasionally in the habit of contrasting with 'sensuality' under the name of 'love'. In all these connections egoism is what is self-evident and constant, while narcissism is the variable element. The opposite to egoism, *altruism*, does not, as a concept, coincide with libidinal object-cathexis, but is distinguished from it by the absence of longings for sexual satisfaction. When someone is completely in love, however, altruism converges with libidinal object cathexis. As a rule the sexual object attracts a portion of the ego's narcissism to itself, and this becomes noticeable as what is known as the 'sexual overvaluation' of the object. If in addition there is an altruistic transposition of egoism on to the sexual object, the object becomes supremely powerful; it has, as it were, absorbed the ego.

You will find it refreshing, I believe, if, after what is the essentially dry imagery of science, I present you with a poetic representation of the economic contrast between narcissism and being in love. Here is a quotation from Goethe's *Westöstlicher Diwan*:

ZULEIKA

The slave, the lord of victories,
The crowd, when'er you ask, confess
In sense of personal being lies
A child of earth's chief happiness.

There's not a life we need refuse
If our true self we do not miss,
There's not a thing we may not lose
If one remain the man one is.

HATEM

So it is held, so well may be;
But down a different track I come;
Of all the bliss earth holds for me
I in Zuleika find the sum.

Does she expend her being on me,
Myself grows to myself of cost;
Turns she away, then instantly
I to my very self am lost.

That day with Hatem all were over;
And yet I should but change my state;
Swift, should she grace some happy lover,
In him I were incorporate.

My second remark is a supplement to the theory of dreams. We cannot explain the origin of dreams unless we adopt the hypothesis that the repressed unconscious has achieved some degree of independence of the ego, so that it does not acquiesce in the wish to sleep and retains its cathexes even when all the object-cathexes depending on the ego have been withdrawn in order to encourage sleep. Only if that is so can we understand how the unconscious can make use of the lifting or reduction of the censorship which occurs at night, and can succeed in obtaining control over the day's residues so as to construct a forbidden dream-wish out of their material. On the other hand, it may be that these day's residues have to thank an already existing connection with the repressed unconscious for some of their resistance to the withdrawal of libido commanded by the wish to sleep. We will, then, insert this dynamically important feature into our view of the formation of dreams by way of supplement.

Organic illness, painful stimulation or inflammation of an organ, creates a condition which clearly results in a detachment of the libido from its objects. The libido which is withdrawn is found in the ego once more, as an increased cathexis of the diseased part of the body. One may venture to assert, indeed, that the withdrawal of the libido from its objects in these circumstances is more striking than the diversion of egoistic interest from the external world. This seems to offer us a path to an understanding of hypochondria, in which an organ excites the ego's attention in the same way, without being ill so far as we can perceive.

But I shall resist the temptation of going further here or of discussing other situations which can be understood or pictured if we adopt the hypothesis that the object-libido may withdraw into the ego - for I am obliged to meet two objections which, as I know, are now attracting your attention. In the first place you want to call me to account because in talking of sleep, illness and similar situations I invariably try to separate libido from interest, sexual from ego-instincts, where observations can be fully satisfied by the hypothesis of a single and uniform energy which, being freely mobile, cathects now the object and now the ego, in obedience to one or the other instinct. And in the second place you want to know how I can venture to treat the detaching of the libido from the object as the source of a pathological state, when a transposition of this kind of object-libido into ego-libido (or, more generally, into ego-energy) is among the normal processes of mental dynamics which are repeated daily and every night.

Here is my reply. Your first objection sounds well enough. Consideration of the states of sleep, of illness and of being in love in themselves would probably never have led us to distinguish an ego-libido from an object-libido or libido from interest. But there you are neglecting the investigations from which we started and in the light of which we now look at the mental situations under discussion. The differentiation between libido and interest - that is to say, between the sexual and the self-preservative instincts - was forced upon us by our discovery of the conflict out of which the transference neuroses arise. Since then we cannot give it up. The hypothesis that object-libido can be transformed into ego-libido, that we must therefore take an ego-libido into account, seems to us the only one which is able to resolve the enigma of what are termed the narcissistic neuroses - dementia praecox, for instance - and to account for the resemblances and dissimilarities between them and hysteria or obsessions. We are now applying to illness, sleep and being in love what we have elsewhere found inescapably established. We should proceed further with applications of this kind and see where they will take us to. The only thesis which is not an immediate precipitate of our analytic experience is to the effect that libido remains libido, whether it is directed to objects or to one's own ego, and never turns into egoistic interest, and the converse is also true. This thesis, however, is equivalent to the separation between the sexual and ego-instincts which we have already considered critically and to which we shall continue to hold for heuristic reasons until its possible collapse.

Your second observation, too, raises a justifiable question, but it is aimed in the wrong direction. It is true that a withdrawal of the object-libido into the ego is not directly pathogenic; it takes place, indeed, as we know, every time before we go to sleep, only to be reversed when we wake up. The amoeba withdraws its protrusions only to send them out again at the first opportunity. But it is quite a different thing when a particular, very energetic process forces a withdrawal of libido from objects. Here the libido that has become narcissistic cannot find its way back to objects, and this interference with the libido's mobility certainly becomes pathogenic. It seems that an accumulation of narcissistic libido beyond a certain amount is not tolerated. We may even imagine that it was for that very reason that object-cathexes originally came about, that the ego was obliged to send out its libido so as not to fall ill as a result of its being dammed up. If it lay within our plan to go more deeply into dementia praecox, I would show you that the process which detaches the libido from objects and cuts off its return to them is closely related to the process of repression and is to be looked at as its counterpart. But you would, first and foremost, find yourselves on familiar ground when you learnt that the determinants of this process are almost identical - so far as we know at present - with those of repression. The conflict seems to be the same and to be carried on between the same forces. If the outcome is so different from, for instance, that in hysteria, the reason can only depend on a difference in innate disposition. The weak spot in the libidinal development of these patients lies in a different phase; the determining fixation, which, as you will recollect, permits the irruption that leads to the formation of symptoms, lies elsewhere, probably in the stage of primitive narcissism to which dementia praecox returns in its final outcome. It is very remarkable that in the case of all the narcissistic neuroses we have to assume fixation points for the libido going back to far earlier phases of development than in hysteria or obsessional neurosis. As you heard, however, the concepts which we arrived at during our study of the transference neuroses are adequate in helping us to find our way about in the narcissistic neuroses which are so much more severe in practice. The conformities go very far; at bottom the field of phenomena is the same. And you can imagine how small a prospect anyone has of explaining these disorders (which belong within the sphere of psychiatry) who is not forearmed for his task with an analytic knowledge of the transference neuroses.

The clinical picture of dementia praecox (which, incidentally, is very changeable) is not determined exclusively by the symptoms arising from the forcing away of the libido on objects and its accumulation in the ego as narcissistic libido. A large part, rather, is played by other phenomena, which are derived from efforts of the libido to attain objects once more and which thus correspond to an attempt at restitution or recovery. These latter symptoms are indeed the more striking and noisy; they exhibit an undeniable resemblance to those of hysteria or, less frequently, of obsessional neurosis, but nevertheless differ from them in every respect. It seems as though in dementia praecox the libido, in its efforts once more to reach objects (that is, the presentations of objects), does in fact snatch hold something of them, but, as it were, only their shadows - I mean the word-presentations belonging to them. I cannot say more about this now, but I believe that this behaviour of the libido as it strives to find its way back has enabled us to obtain an insight into what really constitutes the difference between a conscious and an unconscious idea.

I have now led you into the region in which the next advances in the work of analysis are to be expected. Since we have ventured to operate with the concept of ego-libido the narcissistic neuroses have become accessible to us; the task before us is to arrive at a dynamic elucidation of these disorders and at the same time to complete our knowledge of mental life by coming to understand the ego. The ego-psychology after which we are seeking must not be based on the data of our self-perceptions but (as in the case of the libido) on the analysis of disturbances and disruptions of the ego. It is likely that we shall have a low opinion of our present knowledge of the vicissitudes of the libido, which we have gained from a study of the transference neuroses, when we have achieved this greater task. But hitherto we have not made much progress with it. The narcissistic neuroses can scarcely be attacked with the technique that has served us with the transference neuroses. You will soon learn why. What always happens with them is that, after proceeding for a short distance, we come up against a wall which brings us to a stop. Even with the transference neuroses, as you know, we met with barriers of resistance, but we were able to demolish them bit by bit. In the narcissistic neuroses the resistance is unconquerable; at the most, we are able to cast an inquisitive glance over the top of the wall and spy out what is going on on the other side of it. Our technical methods must accordingly be replaced by others; and we do not know yet whether we shall succeed in finding substitute. Nevertheless, we have no lack of material with these patients either. They make a large number of remarks, even if they do not answer our questions, and for the time being it is our business to interpret these remarks with the help of the understanding we have gained from the symptoms of the transference neuroses. The agreement is great enough to guarantee us some initial advantage. It remains to be seen how far this technique will take us.

There are difficulties in addition which hold up our advance. The narcissistic disorders and the psychoses related to them can only be deciphered by observers who have been trained through the analytic study of the transference neuroses. But our psychiatrists are not students of psycho-analysis and we psychoanalysts see too few psychiatric cases. A race of psychiatrists must first grow up who have passed through the school of psycho-analysis as a preparatory science. A start in that direction is now being made in America, where very many leading psychiatrists lecture to students on the theories of psycho-analysis and where the proprietors of institutions and the directors of insane asylums endeavour to observe their patients in conformity with those theories. Nevertheless we too, over here, have succeeded sometimes in casting a glance over the narcissistic wall and in what follows I shall tell you a little of what we think we have detected.

The form of disease known as paranoia, chronic systematic insanity, occupies an unsettled position in the attempts at classification made by present-day psychiatry. There is, however, no doubt of its close affinity to dementia praecox. I once ventured to suggest that paranoia and dementia praecox should be brought together under the common designation of 'paraphrenia'. The forms of paranoia are described according to their content as megalomania, persecution mania, erotomania, delusions of jealousy, and so on. We shall not expect anything much in the way of an attempt at an explanation from psychiatry. Here is an example of one, though, it is true, one that is out of date and does not carry much weight - an attempt to derive one symptom from another by means of an intellectual rationalization: it is suggested that the patient, who, owing to a primary disposition, believes that he is being persecuted, infers from his persecution that he must be someone of quite particular importance and so develops megalomania. According to our analytic view the megalomania is the direct result of a magnification of the ego due to the drawing in of the libidinal object-cathexes - a secondary narcissism which is a return of the original early infantile one. We have, however, made a few observations of persecution mania which have induced us to follow a particular track. The first thing that struck us was that in the large majority of cases the persecutor was of the same sex as the persecuted patient. This was still open to an innocent explanation; but in a few cases that were thoroughly studied it was clear that the person of the same sex whom the patient loved most had, since his illness, been turned into his persecutor. This made a further development possible: namely, the replacement of the beloved person, along the line of familiar resemblances, by someone else - for instance, a father by a schoolmaster or by some superior. Experiences of this kind in ever increasing numbers led us to conclude that *paranoia persecutoria* is the form of the disease in which a person is defending himself against a homosexual impulse which has become too powerful. The change over from affection to hatred, which, it is well known, may become a serious threat to the life of the loved and hated object, corresponds in such cases to the transformation of libidinal impulses into anxiety which is a regular outcome of the process of repression. Listen, for instance, to what is, once again, the most recent instance of my observations in this connection.

A young doctor had to be expelled from the town in which. he lived because he had threatened the life of the son of a university professor residing there, who had up till then been his greatest friend. He attributed really fiendish intentions and demonic power to this former friend, whom he regarded as responsible for all the misfortunes that had befallen his family in recent years, for every piece of ill-luck whether in his home or in his social life. But that was not all. He believed that this bad friend and the friend's father, the Professor, had caused the war, too, and brought the Russians into the country. His friend had forfeited his life a thousand times, and our patient was convinced that the criminal's death would put an end to every evil. Yet his affection for him was still so strong that it had paralysed his hand when, on one occasion, he had an opportunity of shooting down his enemy at close range. In the course of the short conversations I had with the patient, it came to light that their friendship went back far into their schooldays. Once at least it had overstepped the bounds of friendship: a night which they had spent together had been an occasion for complete sexual intercourse. Our patient had never acquired the emotional relation to women which would have corresponded to his age and his attractive personality. He had once been engaged to a beautiful young girl of good social position; but she had broken off the engagement because she found that her *fiancé* was without any affection. Years later, his illness broke out just at the moment when he had succeeded for the first time in satisfying a woman completely. When this woman embraced him in gratitude and devotion, he suddenly had a mysterious pain that went round the top of his head like a sharp cut. Later on he interpreted this sensation as though an incision were being made at an autopsy for exposing the brain. And as his friend had become a pathological anatomist, it slowly dawned on him that he alone could have sent this last woman to him to seduce him- From that point onwards his eyes were opened to the other persecutions to which he believed he had been made a victim by the machinations of his one-time friend.

But what about the cases in which the persecutor is not of the same sex as the patient and which appear, therefore, to contradict our explanation of their being a defence against homosexual libido? A little time ago I had an opportunity of examining such a case and was able to derive a confirmation from the apparent contradiction. A girl, who believed she was being persecuted by a man with whom she had had affectionate assignations on two occasions, had in fact first had a delusion that was directed against a woman who could be looked on as a substitute for her mother. It was only after her second assignation that she took the step of detaching the delusion from the woman and transferring it to the man. To begin with, therefore, the precondition of the persecutor being of the same sex as the patient was fulfilled in this case too. In making a complaint to a lawyer and to a doctor, the patient made no mention of this preliminary stage of her delusion and thus gave rise to an appearance of there being a contradiction of our explanation of paranoia.

Homosexual object-choice originally lies closer to narcissism than does the heterosexual kind. When it is a question, therefore, of repelling an undesirably strong homosexual impulse, the path back to narcissism is made particularly easy. Hitherto I have had very little opportunity of talking to you about the foundations of erotic life so far as we have discovered them, and it is too late now to catch up on the omission. This much, however, I can emphasize to you. Object-choice, the step forward in the development of the libido which is made after the narcissistic stage, can take place according to two different types: either according to the *narcissistic type*, where the subject's own ego is replaced by another one that is as similar as possible, or according to the *attachment type*, where people who have become precious through satisfying the other vital needs are chosen as objects by the libido as well. A strong libidinal fixation to the narcissistic type of object-choice is to be included in the predisposition to manifest homosexuality.

You will recall that at our first meeting of the present academic year I described a case to you of a woman suffering from delusions of jealousy. Now that we are so near its end you would no doubt like to hear how delusions are explained by psycho-analysis. But I have less to tell you about that than you expect. The fact that a delusion cannot be shaken by logical arguments or real experiences is explained in the same way as in the case of an obsession - by its relation to the unconscious, which is represented and held down by the delusion or by the obsession. The difference between the two is based on the difference between the topography and dynamics of the two illnesses.

As with paranoia, so also with melancholia (of which, incidentally, many different clinical forms have been described) we have found a point at which it has become possible to obtain some insight into the internal structure of the disease. We have discovered that the self-reproaches, with which these melancholic patients torment themselves in the most merciless fashion, in fact apply to another person, the sexual object which they have lost or which has become valueless to them through its own fault. From this we can conclude that the melancholic has, it is true, withdrawn his libido from the object, but that, by a process which we must call 'narcissistic identification', the object has been set up in the ego itself, has been as it were, projected on to the ego. (Here I can only give you a pictorial description and not an ordered account on topographical and dynamic lines.) The subject's own ego is then treated like the object that has been abandoned, and it is subjected to all the acts of aggression and expressions of vengefulness which have been aimed at the object. A melancholic's propensity to suicide is also made more intelligible if we consider that the patient's embitterment strikes with a single blow at his own ego and at the loved and hated object. In melancholia, as well as in other narcissistic disorders, a particular trait in the patient's emotional life emerges with peculiar emphasis - what, since Bleuler, we have been accustomed to describe as 'ambivalence'. By this we mean the direction towards the same person of contrary - affectionate and hostile - feelings. Unluckily I have been unable in the course of these lectures to tell you more about this emotional ambivalence.

In addition to narcissistic identification, there is a hysterical kind, which has been familiar to us very much longer. I wish it were possible to illustrate for you the differences between the two forms by a few clear specifications. There is something I can tell you about the periodic and cyclical forms of melancholia which I am sure you will be glad to hear. For in favourable circumstances - I have experienced this twice - it is possible by analytic treatment in the lucid intervals to prevent the return of the condition in the same or the opposite emotional mood. We learn from such cases that in melancholia and mania we are concerned once more with a special method of dealing with a conflict whose underlying determinants agree precisely with those of the other neuroses. You can imagine how much more there is for psycho-analysis to learn in this field of knowledge.

I told you too that we hoped that the analysis of the narcissistic disorders would give us an insight into the way in which our ego is put together and built up out of different agencies. We have already made a start with this at one point. From the analysis of delusions of observation we have drawn the conclusion that there actually exists in the ego an agency which unceasingly observes, criticizes and compares, and in that way sets itself over against the other part of the ego. We believe, therefore, that the patient is betraying a truth to us which is not yet sufficiently appreciated when he complains that he is spied upon and observed at every step he takes and that every one of his thoughts is reported and criticized. His only mistake is in regarding this uncomfortable power as something alien to him and placing it outside himself. He senses an agency holding sway in his ego which measures his actual ego and each of its activities by an *ideal ego* that he has created for himself in the course of his development. We believe, too, that this creation was made with the intention of re-establishing the self-satisfaction which was attached to primary infantile narcissism but which since then has suffered so many disturbances and mortifications. We know the self-observing agency as the ego-censor, the conscience; it is this that exercises the dream-censorship during the night, from which the repressions of inadmissible wishful impulses proceed. When in delusions of observation it becomes split up, it reveals to us its origin from the influences of parents, educators and social environment - from an identification with some of these model figures.

These are a few of the findings which have hitherto been reached from the application of psycho-analysis to the narcissistic disorders. No doubt there are not yet enough of them and they still lack the precision which can only be attained from established familiarity with a new field. We owe all of them to a use of the concept of ego-libido or narcissistic libido, by whose help we can extend to the narcissistic neuroses the views which have proved their value with the transference neuroses. Now, however, you will ask whether it is possible that we shall succeed in subsuming all the disturbances of the narcissistic illnesses and of the psychoses under the libido theory, whether we look upon the libidinal factor in mental life as universally guilty of the causation of illness, and need never attribute the responsibility for it to changes in the functioning of the self-preservative instinct. Well, Ladies and Gentlemen, this question seems to me to call for no urgent reply, and, above all, not to be ripe for judgement. We can confidently leave it over in expectation of the progress of our scientific work. I should not be surprised if it turned out that the power to produce pathogenic effects was in fact a prerogative of the libidinal instincts, so that the libido theory could celebrate its triumph all along the line from the simplest 'actual' neurosis to the most severe alienation of the personality. We after all know that it is a characteristic feature of the libido that it struggles against submitting to the reality of the universe - to Ananke. But I regard it as extremely probable that the ego-instincts are carried along secondarily by the pathogenic instigation of the libido and forced into functional disturbances. Nor can I think that it would be a disaster to the trend of our researches, if what lies before us is the discovery that in severe psychoses the ego-instincts themselves have gone astray as a primary fact. The future will give the answer - to you, at any rate.

Let me once more, however, return for a moment to anxiety, to throw light on a last obscurity that we left there. I have said that there is something that does not tally with the relation (so thoroughly recognized apart from this) between anxiety and libido: the fact, namely, that realistic anxiety in face of a danger seems to be a manifestation of the self-preservative instinct - which, after all, can scarcely be disputed. How would it be, though, if what was responsible for the affect of anxiety was not the egoistic ego-instincts but the ego-libido? After all, the state of anxiety is in every instance inexpedient, and its inexpedience becomes obvious if it reaches a fairly high pitch. In such cases it interferes with action, whether flight or defence, which alone is expedient and alone serves the cause of self-preservation. If, therefore, we attribute the affective portion of realistic anxiety to ego-libido and the accompanying action to the self-preservative instinct, we shall have got rid of the theoretical difficulty. After all, you do not seriously believe that one runs away because one feels anxiety? No. One feels anxiety and one runs away for a common motive, which is roused by the perception of danger. People who have been through a great mortal danger tell us that they were not at all afraid but merely acted - for instance, that they aimed their rifle at the wild beast - and that is unquestionably what was most expedient.

LECTURE XXVII

TRANSFERENCE

LADIES AND GENTLEMEN, - Since we are now drawing towards the end of our discussions, there is a particular expectation which will be in your minds and which should not be disappointed. You no doubt suppose that I would not have led you through thick and thin of the subject-matter of psycho-analysis only to dismiss you at the end without saying a word about therapy, on which, after all, the possibility of practising psycho-analysis at all is based. The subject, moreover, is one that I cannot withhold from you, since what you learn in connection with it will enable you to make the acquaintance of a new fact in whose absence your understanding of the illnesses investigated by us will remain most markedly incomplete.

You do not, I know, expect me to initiate you into the technique by which analysis for therapeutic ends should be carried out. You only want to know in the most general way the method by which psycho-analytic therapy operates and what, roughly, it accomplishes. And you have an indisputable right to learn this. I shall not, however, tell it you but shall insist on your discovering it for yourselves.

Think it over! You have learnt all that is essential about the determinants of falling ill as well as all the factors that come into effect *after* the patient has fallen ill. Where do these leave room for any therapeutic influence? In the first place there is hereditary disposition. We have not talked about it very often because it is emphatically stressed from other directions and we have nothing new to say about it. But do not suppose that we underestimate it; precisely as therapists we come to realize its power clearly enough. In any case we can do nothing to alter it; we too must take it as something given, which sets a limit to our efforts. Next there is the influence of early experiences in childhood, to which we are in the habit of giving prominence in analysis: they belong to the past and we cannot undo them. Then comes everything that we have summarized as 'real frustration' - the misfortunes of life from which arise deprivation of love, poverty, family quarrels, ill-judged choice of a partner in marriage, unfavourable social circumstances, and the strictness of the ethical standards to whose pressure the individual is subject. Here, to be sure, there would be handles enough for a very effective therapy, but it would have to be of the kind which Viennese folklore attributes to the Emperor Joseph - the benevolent interference of a powerful personage before whose will people bow and difficulties vanish. But who are we, that we should be able to adopt benevolence of this kind as an instrument of our therapy? Poor ourselves and socially powerless, and compelled to earn our livelihood from our medical activity, we are not even in a position to extend our efforts to people without means, as other doctors with other methods of treatment are after all able to do. Our therapy is too time-consuming and too laborious for that to be possible. Perhaps, however, you are clutching at one of the factors I have mentioned and believe that there you have found the point at which our influence can make its attack. If the ethical restrictions demanded by society play a part in the deprivation imposed on the patient, treatment can, after all, give him the courage, or perhaps a direct injunction, to disregard those barriers and achieve satisfaction and recovery while forgoing the fulfilment of an ideal that is exalted, but so often not adhered to, by society. The patient will thus become healthy by 'living a full life' sexually. This, it is true, casts a shadow on analytic treatment for not serving general morality. What it has given to the individual it will have taken from the community.

But, Ladies and Gentlemen, who has so seriously misinformed you? A recommendation to the patient to 'live a full life' sexually could not possibly play a part in analytic therapy - if only because we ourselves have declared that an obstinate conflict is taking place in him between a libidinal impulse and sexual repression, between a sensual and an ascetic trend. This conflict would not be solved by our helping one of these trends to victory over its opponent. We see, indeed, that in neurotics asceticism has the upper hand; and the consequence of this is precisely that the suppressed sexual tendency finds a way out in symptoms. If, on the contrary, we were to secure victory for sensuality, then the sexual repression that had been put on one side would necessarily be replaced by symptom. Neither of these two alternative decisions could end the internal conflict; in either case one party to it would remain unsatisfied. There are only a few cases in which the conflict is so unstable that a factor such as the doctor's taking sides could decide it; and such cases do not in fact stand in need of analytic treatment. Anyone on whom the doctor could have so much influence would have found the same way out without the doctor. You must be aware that if an abstinent young man decides in favour of illicit sexual intercourse or if an unsatisfied wife seeks relief with another man, they have not as a rule waited for permission from a doctor or even from their analyst.

In this connection people usually overlook the one essential point - that the pathogenic conflict in neurotics is not to be confused with a normal struggle between mental impulses both of which are on the same psychological footing. In the former case the dissension is between two powers, one of which has made its way to the stage of what is preconscious or conscious while the other has been held back at the stage of the unconscious. For that reason the conflict cannot be brought to an issue; the disputants can no more come to grips than, in the familiar simile, a polar bear and a whale. A true decision can only be reached when they both meet on the same ground. To make this possible is, I think, the sole task of our therapy.

Moreover, I can assure you that you are misinformed if you suppose that advice and guidance in the affairs of life play an integral part in analytic influence. On the contrary, so far as possible we avoid the role of a mentor such as this and there is nothing we would rather bring about than the patient should make his decisions for himself. With this purpose, too, we require him to postpone for the term of his treatment any vital decisions on choice of a profession, business undertakings, marriage or divorce, and only to put them in practice when the treatment is finished. You must admit that all this is different from what you pictured. Only in the case of some very youthful or quite helpless or unstable individuals are we unable to put the desired limitation of our role into effect. With them we have to combine the functions of a doctor and an educator; but when this is so we are quite conscious of our responsibility and behave with the necessary caution.

But you must not conclude from my eagerness in defending myself against the charge that neurotics are encouraged in analytic treatment to live a full life - you must not conclude from this that we influence them in favour of conventional virtue. That is at least as far from being the case. It is true that we are not reformers but merely observers; nevertheless, we cannot help observing with a critical eye and we have found it impossible to side with conventional sexual morality or to form a very high opinion of the manner in which society attempts the practical regulation of the problems of sexual life. We can present society with a blunt calculation that what is described as its morality calls for a bigger sacrifice than it is worth and that its proceedings are not based on honesty and do not display wisdom. We do not keep such criticisms from our patients' ears, we accustom them to giving unprejudiced consideration to sexual matters no less than to any others; and if, having grown independent after the completion of their treatment, they decide on their own judgement in favour of some midway position between living a full life and absolute asceticism, we feel our conscience clear whatever their choice. We tell ourselves that anyone who has succeeded in educating himself to truth about himself is permanently defended against the danger of immorality, even though his standard of morality may differ in some respect from that which is customary in society. Moreover, we must guard against over-estimating the importance of the part played by the question of abstinence in influencing neuroses. Only in a minority of cases can the pathogenic situation of frustration and the subsequent damming-up of libido be brought to an end by the sort of sexual intercourse that can be procured without much trouble.

Thus you cannot explain the therapeutic effect of psycho-analysis by its permitting a full sexual life. Look around, then, for something else. I fancy that, while I was rejecting this suggestion of yours, one remark of mine put you on the right track. What we make use of must no doubt be the replacing of what is unconscious by what is conscious, the translation of what is unconscious into what is conscious. Yes, that is it. By carrying what is unconscious on into what is conscious, we lift the repressions, we remove the preconditions for the formation of symptoms, we transform the pathogenic conflict to a normal one for which it must be possible somehow to find a solution. All that we bring about in a patient is this single psychical change: the length to which it is carried is the measure of the help we provide. Where no repressions (or analogous psychical processes) can be undone, our therapy nothing to expect.

We can express the aim of our efforts in a variety of formulas: making conscious what is unconscious, lifting repressions, filling gaps in the memory - all these amount to the same thing. But perhaps you will be dissatisfied by this admission. You had formed a different picture of the return to health of a neurotic patient - that, after submitting to the tedious hours of a psycho-analysis, he would become another man; but the total result, so it seems, is that he has rather less that is unconscious and rather more that is conscious in him than he had before. The fact is that you are probably under-estimating the importance of an internal change of this kind. The neurotic who is cured has really become another man, though a bottom, of course, he has remained the same; that is to say, he has become what he might have become at best under the most favourable conditions. But that is a very great deal. If you now hear all that has to be done and what efforts it needs to bring about this apparently trivial change in a man's mental life, you will no doubt begin to realize the importance of this difference in psychical levels.

I will digress for a moment to ask if you know what is meant by a causal therapy. That is how we describe procedure which does not take the symptoms of an illness as its point of attack but sets about removing its *causes*. Well, then, is our psycho-analytic method a causal therapy or not? The reply is not a simple one, but it may perhaps give us an opportunity of realizing the worthlessness of a question framed in this way. In so far as analytic therapy does not make it its first task to remove the symptoms, it is behaving like a causal therapy. In another respect, you may say, it is not. For we long ago traced the causal chain back through the repressions to the instinctual dispositions, their relative intensities in the constitution and the deviations in the course of their development. Supposing, now, that it was possible, by some chemical means, perhaps, to interfere in this mechanism, to increase or diminish the quantity of libido present at a given time or to strengthen one instinct at the cost of another - this then would be a causal therapy in the true sense of the word, for which our analysis would have carried out the indispensable preliminary work of reconnaissance. At present, as you know, there is no question of any such method of influencing libidinal processes; with our psychical therapy we attack at a different point in the combination - not exactly at what we know are the roots of the phenomena, but nevertheless far enough away from the symptoms, at a point which has been made accessible to us by some very remarkable circumstances.

What, then, must we do in order to replace what is unconscious in our patients by what is conscious? There was a time when we thought this was a very simple matter: all that was necessary was for us to discover this unconscious material and communicate it to the patient. But we know already that this was a short-sighted error. *Our* knowledge about the unconscious material is not equivalent to *his* knowledge; if we communicate our knowledge to him, he does not receive it *instead of* his unconscious material but *beside* it; and that makes very little change in it. We must rather picture this unconscious material topographically, we must look for it in his memory at the place where it became unconscious owing to a repression. The repression must be got rid of - after which the substitution of the conscious material for the unconscious can proceed smoothly. How, then, do we lift a repression of this kind? Here our task enters a second phase. First, the search for the repression and then the removal of the resistance which maintains the repression.

How do we remove the resistance? In the same way: by discovering it and showing it to the patient. Indeed, the resistance too is derived from a repression - from the same one that we are endeavouring to resolve, or from one that took place earlier. It was set up by the anticathexis which arose in order to repress the objectionable impulse. Thus we now do the same thing that we tried to do to begin with: interpret, discover and communicate; but now we are doing it at the right place. The anticathexis or the resistance does not form part of the unconscious but of the ego, which is our collaborator, and is so even if it is not conscious. As we know, the word 'unconscious' is being used here in two senses: on the one hand as a phenomenon and on the other as a system. This sounds very difficult and obscure; but is it not only repeating what we have already said in earlier passages? We have long been prepared for it. We expect that this resistance will be given up and the anticathexis withdrawn when our interpretation has made it possible for the ego to recognize it. What are the motive forces that we work with in such a case? First with the patient's desire for recovery, which has induced him to take part with us in our joint work, and secondly with the help of his intelligence, to which we give support by our interpretation. There is no doubt that it is easier for the patient's intelligence to recognize the resistance and to find the translation corresponding to what is repressed if we have previously given him the appropriate anticipatory ideas. If I say to you: 'Look up at the sky! There's a balloon there!' you will discover it much more easily than if I simply tell you to look up and see if you can see anything. In the same way, a student who is looking through a microscope for the first time is instructed by his teacher as to what he will see; otherwise he does not see it at all, though it is there and visible.

And now for the fact! In a whole number of nervous diseases - in hysteria, anxiety states, obsessional neurosis - our expectation is fulfilled. By searching for the repression in this way, by uncovering the resistances, by pointing out what is repressed, we really succeed in accomplishing our task - that is, in overcoming the resistances, lifting the repression and transforming the unconscious material into conscious. In doing so we gain the clearest impression of the way in which a violent struggle takes place in the patient's mind about the overcoming of each resistance - a *normal* mental struggle, on the same psychological ground, between the motives which seek to maintain the anticathexis and those which are prepared to give it up. The former are the old motives which in the past put the repression into effect; among the latter are the newly arrived ones which, we may hope, will decide the conflict in our favour. We have succeeded in reviving the old conflict which led to repression and in bringing up for revision the process that was then decided. The new material that we produce includes, first the reminder that the earlier decision led to illness and the promise that a different path will lead to recovery, and, second, the enormous change in all the circumstances that has taken place since the time of the original rejection. Then the ego was feeble, infantile, and may perhaps have had grounds for banning the demands of the libido as a danger. To-day it has grown strong and experienced, and moreover has a helper at and in the shape of the doctor. Thus we may expect to lead the revived conflict to a better outcome than that which ended in repression, and, as I have said, in hysteria and in the anxiety and obsessional neuroses success proves us in general to be correct,

There are, however, other forms of illness in which, in spite of the conditions being the same, our therapeutic procedure is never successful. In them, too, it had been a question of an original conflict between the ego and the libido which led to repression - though this may call for a different topographical description; in them, too, it is possible to trace the points in the patient's life at which the repressions occurred; we make use of the same procedure, are ready to make the same promises and give the same help by the offer of anticipatory ideas; and once again the lapse of time between the repressions and the present day favours a different outcome to the conflict. And yet we do not succeed in lifting a single resistance or getting rid of a single repression. These patients, paranoics, melancholics, sufferers from dementia praecox, remain on the whole unaffected and proof against psycho-analytic therapy. What can be the reason for this? Not any lack of intelligence. A certain amount of intellectual capacity is naturally required in our patients; but there is certainly no lack of it in, for instance, the extremely shrewd combinatory paranoics. Nor do any of the other motives seem to be absent. Thus the melancholics have a very high degree of consciousness, absent in paranoics, that they are ill and that that is why they suffer so much; but this does not make them more accessible. We are faced here by a fact which we do not understand and which therefore leads us to doubt whether we have really understood all the determinants of our possible success with the other neuroses.

If we continue to concern ourselves only with our hysterics and obsessional neurotics, we are soon met by a second fact for which we were not in the least prepared. For after a while we cannot help noticing that these patients behave in a quite peculiar manner to us. We believed, to be sure, that we had reckoned with all the motives concerned in the treatment, that we had completely rationalized the situation between us and the patients so that it could be looked over at a glance like a sum in arithmetic; yet, in spite of all this, something seems to creep in which has not been taken into account in our sum. This unexpected novelty itself takes many shapes, and I will begin by describing to you the commoner and more easily understandable of the forms in which it appears.

We notice, then, that the patient, who ought to want nothing else but to find a way out of his distressing conflict, develops a special interest in the person of the doctor. Everything connected with the doctor seems to be more important to him than his own affairs and to be diverting him from his illness. For a time, accordingly, relations with him become very agreeable; he is particularly obliging, tries wherever possible to show his gratitude, reveals refinements and merits in his nature which we should not, perhaps, have expected to find in him. The doctor, too, thereupon forms a favourable opinion of the patient and appreciates the good fortune which has enabled him to give his assistance to such a particularly valuable personality. If the doctor has an opportunity of talking to the patient's relatives, he learns to his satisfaction that the liking is a mutual one. The patient never tires in his home of praising the doctor and of extolling ever new qualities in him. 'He's enthusiastic about you,' say his relatives, 'he trusts you blindly; everything you say is like a revelation to him.' Here and there someone in this chorus has sharper eyes and says: 'It's becoming a bore, the way he talks of nothing else but you and has your name on his lips all the time.'

Let us hope that the doctor is modest enough to attribute his patient's high opinion of him to the hopes he can rouse in him and to the widening of his intellectual horizon by the surprising and liberating enlightenment that the treatment brings with it. Under these conditions the analysis makes fine progress too. The patient understands what is interpreted to him and becomes engrossed in the tasks set him by the treatment; the material of memories and associations floods in upon him in plenty, the certainty and appositeness of his interpretations are a surprise to the doctor, and the latter can only take note with satisfaction that here is a patient who readily accepts all the psychological novelties which are apt to provoke the most bitter contradiction among healthy people in the outside world. Moreover the cordial relations that prevail during the work of analysis are accompanied by an objective improvement, which is recognized on all sides, in the patient's illness.

But such fine weather cannot last for ever. One day it clouds over. Difficulties arise in the treatment; the patient declares that nothing more occurs to him. He gives the clearest impression of his interest being no longer in the work and of his cheerfully disregarding the instructions given him to say everything that comes into his head and not to give way to any critical obstacle to doing so. He behaves as though he were outside the treatment and as though he had not made this agreement with the doctor. He is evidently occupied with something, but intends to keep it to himself. This is a situation that is dangerous for the treatment. We are unmistakably confronted by a formidable resistance. But what has happened to account for it?

If we are able once more to clarify the position, we find that the cause of the disturbance is that the patient has transferred on to the doctor intense feelings of affection which are justified neither by the doctor's behaviour nor by the situation that has developed during the treatment. The form in which this affection is expressed and what its aims are depend of course on the personal relation between the two people involved. If those concerned are a young girl and a youngish man, we shall get the impression of a normal case of falling in love; we shall find it understandable that a girl should fall in love with a man with whom she can be much alone and talk of intimate things and who has the advantage of having met her as a helpful superior; and we shall probably overlook the fact that what we should expect from a neurotic girl would rather be an impediment in her capacity for love. The further the personal relations between doctor and patient diverge from this supposed case, the more we shall be surprised to find nevertheless the same emotional relationship constantly recurring. It may still pass muster if a woman who is unhappy in her marriage appears to be seized with a serious passion for a doctor who is still unattached, if she is ready to seek a divorce in order to be his or if, where there are social obstacles, she even expresses no hesitation about entering into a secret *liaison* with him. Such things come about even outside psycho-analysis. But in these circumstances we are astonished to hear declarations by married women and girls which bear witness to a quite particular attitude to the therapeutic problem: they had always known, they say, that they could only be cured by love, and before the treatment began they had expected that through this relation they would at last be granted what life had hitherto withheld from them; it had only been in this hope that they had taken so much trouble over the treatment and overcome all the difficulties in communicating their thoughts - and we on our part can add: and had so easily understood what is otherwise so hard to believe. But an admission of this sort surprises us: it throws all our calculations to the winds. Can it be that we have left the most important item out of our account?

And indeed, the greater our experience the less we are able to resist making this correction, though having to do so puts our scientific pretensions to shame. On the first few occasions one might perhaps think that the analytic treatment had come up against a disturbance due to a chance event - an event, that is, not intended and not provoked by it. But when a similar affectionate attachment by the patient to the doctor is repeated regularly in every new case, when it comes to light again and again, under the most unfavourable conditions and where there are positively grotesque incongruities, even in elderly women and in relation to grey-bearded men, even where, in our judgement, there is nothing of any kind to entice - then we must abandon the idea of a chance disturbance and recognize that we are dealing with a phenomenon which is intimately bound up with the nature of the illness itself.

This new fact, which we thus recognize so unwillingly, is known by us as *transference*. We mean a transference of feelings on to the person of the doctor, since we do not believe that the situation in the treatment could justify the development of such feelings. We suspect, on the contrary, that the whole readiness for these feelings is derived from elsewhere, that they were already prepared in the patient and, upon the opportunity offered by the analytic treatment, are transferred on to the person of the doctor. Transference can appear as a passionate demand for love or in more moderate forms; in place of a wish to be loved, a wish can emerge between a girl and an old man to be received as a favourite daughter; the libidinal desire can be toned down into a proposal for an inseparable, but ideally non-sensual, friendship. Some women succeed in sublimating the transference and in moulding it till it achieves a kind of viability; others must express it in its crude, original, and for the most part, impossible form. But at bottom it is always the same, and never allows its origin from the same source to be mistaken.

Before we enquire where we are to find a place for this new fact, I will complete my description of it. What happens with male patients? There at least one might hope to escape the troublesome interference caused by difference of sex and by sexual attraction. Our answer, however, must be much the same as in the case of women. There is the same attachment to the doctor, the same overvaluation of his qualities, the same absorption in his interests, the same jealousy of everyone close to him in real life. The sublimated forms of transference are more frequent between one man and another and straightforward sexual demands are rarer, in proportion as manifest homosexuality is unusual as compared with the other ways in which these instinctual components are employed. With his male patients, again, more often than with women, the doctor comes across a form of expression of the transference which seems at first sight to contradict all our previous descriptions - a hostile or *negative* transference.

I must begin by making it clear that a transference is present in the patient from the beginning of the treatment and for a while is the most powerful motive in its advance. We see no trace of it and need not bother about it so long as it operates in favour of the joint work of analysis. If it then changes into a resistance, we must turn our attention to it and we recognize that it alters its relation to the treatment under two different and contrary conditions: firstly, if as an affectionate trend it has become so powerful, and betrays signs of its origin in a sexual need so clearly, that it inevitably provokes an internal opposition to itself, and, secondly, if it consists of hostile instead of affectionate impulses. The hostile feelings make their appearance as a rule later than the affectionate ones and behind them; their simultaneous presence gives a good picture of the emotional ambivalence which is dominant in the majority of our intimate relations with other people. The hostile feelings are as much an indication of an emotional tie as the affectionate ones, in the same way as defiance signifies dependence as much as obedience does, though with a 'minus' instead of a 'plus' sign before it. We can be in no doubt that the hostile feelings towards the doctor deserve to be called a 'transference', since the situation in the treatment quite certainly offers no adequate grounds for their origin; this necessary view of the negative transference assures us, therefore, that we have not gone wrong in our judgement of the positive or affectionate one.

Where the transference arises, what difficulties it raises for us, how we overcome them and what advantages we eventually derive from it - these are questions to be dealt with in a technical guide to analysis, and I shall only touch on them lightly to-day. It is out of the question for us to yield to the patient's demands deriving from the transference; it would be absurd for us to reject them in an unfriendly, still more in an indignant, manner. We overcome the transference by pointing out to the patient that his feelings do not arise from the present situation and do not apply to the person of the doctor, but that they are repeating something that happened to him earlier. In this way we oblige him to transform his repetition into a memory. By that means the transference, which, whether affectionate or hostile, seemed in every case to constitute the greatest threat to the treatment, becomes its best tool, by whose help the most secret compartments of mental life can be opened.

But I should like to say a few words to you to relieve you of your surprise at the emergence of this unexpected phenomenon. We must not forget that the patient's illness, which we have undertaken to analyse, is not something which has been rounded off and become rigid but that it is still growing and developing like a living organism. The beginning of the treatment does not put an end to this development; when, however, the treatment has obtained mastery over the patient, what happens is that the whole of his illness's new production is concentrated upon a single point - his relation to the doctor. Thus the transference may be compared to the cambium layer in a tree between the wood and the bark, from which the new formation of tissue and the increase in the girth of the trunk derive. When the transference has risen to this significance, work upon the patient's memories retreats far into the background. Thereafter it is not incorrect to say that we are no longer concerned with the patient's earlier illness but with a newly created and transformed neurosis which has taken the former's place. We have followed this new edition of the old disorder from its start, we have observed its origin and growth, and we are especially well able to find our way about in it since, as its object, we are situated at its very centre. All the patient's symptoms have abandoned their original meaning and have taken on a new sense which lies in a relation to the transference; or only such symptoms have persisted as are capable of undergoing such a transformation. But the mastering of this new, artificial neurosis coincides with getting rid of the illness which was originally brought to the treatment - with the accomplishment of our therapeutic task. A person who has become normal and free from the operation of repressed instinctual impulse in his relation to the doctor will remain so in his own life after the doctor has once more withdrawn from it.

The transference possesses this extraordinary, and for the treatment, positively central, importance in hysteria, anxiety hysteria and obsessional neurosis, which are for that reason rightly classed together as 'transference neuroses'. No one who has taken in a full impression of the fact of transference from his analytic work will any longer doubt the nature of the suppressed impulses that obtain expression in the symptoms of these neuroses, and will call for no more powerful evidence of their libidinal character. It may be said that our conviction of the significance of symptoms as substitutive satisfactions of the libido only received its final confirmation after the enlistment of the transference.

There is every reason now for us to improve our earlier dynamic account of the therapeutic process and to bring it into harmony with our new realization. If the patient is to fight his way through the normal conflict with the resistances which we have uncovered for him in the analysis, he is in need of a powerful stimulus which will influence the decision in the sense which we desire, leading to recovery. Otherwise it might happen that he would choose in favour of repeating the earlier outcome and would allow what had been brought up into consciousness to slip back again into repression. At this point what turns the scale in his struggle is not his intellectual insight which is neither strong enough nor free enough for such an achievement - but simply and solely his relation to the doctor. In so far as his transference bears a 'plus' sign, it clothes the doctor with authority and is transformed into belief in his communications and explanations. In the absence of such a transference, or if it is a negative one, the patient would never even give a hearing to the doctor and his arguments. In this his belief is repeating the story of its own development; it is a derivative of love and, to start with, needed no arguments. Only later did he allow them enough room to submit them to examination, provided they were brought forward by someone he loved. Without such supports arguments carried no weight, and in most people's lives they never do. Thus in general a man is only accessible from the intellectual side too, in so far as he is capable of a libidinal cathexis of objects; and we have good reason to recognize and to dread in the amount of his narcissism a barrier against the possibility of being influenced by even the best analytic technique.

A capacity for directing libidinal object-cathexes on to people must of course be attributed to every normal person. The tendency to transference of the neurotics I have spoken of is only an extraordinary increase of this universal characteristic. It would indeed be very strange if a human trait so widespread and so important had never been noticed or appreciated. And in fact it *has* been. Bernheim, with an unerring eye based his theory of hypnotic phenomena on the thesis that everyone is in some way 'suggestible'. His suggestibility was nothing other than the tendency to transference, somewhat too narrowly conceived, so that it did not include negative transference. But Bernheim was never able to say what suggestion actually was and how it came about. For him it was a fundamental fact on whose origin he could throw no light. He did not know that his '*suggestibilité*' depended on sexuality, on the activity of the libido. And it must dawn on us that in our technique we have abandoned hypnosis only to rediscover suggestion in the shape of transference.

But here I will pause, and let you have a word; for I see an objection boiling up in you so fiercely that it would make you incapable of listening if it were not put into words: 'Ah! so you've admitted it at last! You work with the help of suggestion, just like the hypnotists! That is what we've thought for a long time. But, if so, why the roundabout road by way of memories of the past, discovering the unconscious, interpreting and translating back distortions - this immense expenditure of labour, time and money - when the one effective thing is after all only suggestion? Why do you not make direct suggestion against the symptoms, as the others do - the honest hypnotists? Moreover, if you try to excuse yourself for your long detour on the ground that you have made a number of important psychological discoveries which are hidden by direct suggestion - what about the certainty of these discoveries now? Are not they a result of suggestion too, of unintentional suggestion? Is it not possible that you are forcing on the patient what you want and what seems to you correct, in this field as well?'

What you are throwing up at me in this is uncommonly interesting and must be answered. But I cannot do so to-day: we have not the time. Till our next meeting, then. I will answer you, you will see. But to-day I must finish what I have begun. I promised to make you understand by the help of the fact of transference why our therapeutic efforts have no success with the narcissistic neuroses.

I can do so in a few words, and you will see how simply the riddle can be solved and how well everything fits together. Observation shows that sufferers from narcissistic neuroses have no capacity for transference or only insufficient residues of it. They reject the doctor, not with hostility but with indifference. For that reason they cannot be influenced by him either; what he says leaves them cold, makes no impression on them; consequently the mechanism of cure which we carry through with other people - the revival of the pathogenic conflict and the overcoming of the resistance due to repression - cannot be operated with them. They remain as they are. Often they have already undertaken attempts at recovery on their own account which have led to pathological results. We cannot alter this in any way.

On the basis of our clinical impressions we maintained that these patients' object-cathexes must have been given up and that their object-libido must have been transformed into ego-libido. Through this characteristic we distinguished them from the first group of neurotics (sufferers from hysteria, anxiety-hysteria and obsessional neurosis). This suspicion is now confirmed by their behaviour in our attempts at therapy. They manifest no transference and for that reason are inaccessible to our efforts and cannot be cured by us.

LECTURE XXVIII

ANALYTIC THERAPY

LADIES AND GENTLEMEN, - You know what we are going to talk about to-day. You asked me why we do not make use of direct suggestion in psycho-analytic therapy, when we admit that our influence rests essentially on transference - that is, on suggestion; and you added a doubt whether, in view of this predominance of suggestion, we are still able to claim that our psychological discoveries are objective. I promised I would give you a detailed reply.

Direct suggestion is suggestion aimed against the manifestation of the symptoms; it is a struggle between your authority and the motives for the illness. In this you do not concern yourself with these motives; you merely request the patient to suppress their manifestation in symptoms. It makes no difference of principle whether you put the patient under hypnosis or not. Once again Bernheim, with his characteristic perspicacity, maintained that suggestion was the essential element in the phenomena of hypnotism, that hypnosis itself was already a result of suggestion, a suggested state; and he preferred to practise suggestion in a waking state, which can achieve the same effects as suggestion under hypnosis.

Which would you rather hear first on this question - what experience tells us or theoretical considerations?

Let us begin with the former. I was a pupil of Bernheim's, whom I visited at Nancy in 1889 and whose book on suggestion I translated into German. I practised hypnotic treatment for many years, at first by prohibitory suggestion and later in combination with Breuer's method of questioning the patient. I can therefore speak of the results of hypnotic or suggestive therapy on the basis of a wide experience. If, in the words of the old medical aphorism, an ideal therapy should be rapid, reliable and not disagreeable for the patient, Bernheim's method fulfilled at least two of these requirements. It could be carried through much quicker - or, rather, infinitely quicker - than analytic treatment and it caused the patient neither trouble nor unpleasantness. For the doctor it became, in the long run, *monotonous*: in each case, in the same way, with the same ceremonial, forbidding the most variegated symptoms to exist, without being able to learn anything of their sense and meaning. It was hackwork and not a scientific activity, and it recalled magic, incantations and hocus-pocus. That could not weigh, however, against the patient's interest. But the third quality was lacking: the procedure was not reliable in any respect. It could be used with one patient, but not with another; it achieved a great deal with one and very little with another, and one never knew why. Worse than the capriciousness of the procedure was the lack of permanence in its successes. If, after a short time, one had news of the patient once more, the old ailment was back again or its place had been taken by a new one. One might hypnotize him again. But in the background there was the warning given by experienced workers against robbing the patient of his self-reliance by frequently repeated hypnosis and so making him an addict to this kind of therapy as though it were a narcotic. Admittedly sometimes things went entirely as one would wish: after a few efforts, success was complete and permanent. But the conditions determining such a favourable outcome remained unknown. On one occasion a severe condition in a woman, which I had entirely got rid of by a short hypnotic treatment, returned unchanged after the patient had, through no action on my part, got annoyed with me; after a reconciliation, I removed the trouble again and far more thoroughly; yet it returned once more after she had fallen foul of me a second time. On another occasion a woman patient, whom I had repeatedly helped out of neurotic states by hypnosis, suddenly, during the treatment of a specially obstinate situation, threw her arms round my neck. After this one could scarcely avoid, whether one wanted to or not, investigating the question of the nature and origin of one's authority in suggestive treatment.

So much for experiences. They show us that in renouncing direct suggestion we are not giving up anything of irreplaceable value. Now let us add a few reflections to this. The practice of hypnotic therapy makes very small demands on either the patient or the doctor. It agrees most beautifully with the estimate in which neuroses are still held by the majority of doctors. The doctor says to the neurotic patient: 'There's nothing wrong with you, it's only a question of nerves; so I can blow away your trouble in two or three minutes with just a few words.' But our views on the laws of energy are offended by the notion of its being possible to move a great weight by a tiny application of force, attacking it directly, without the outside help of any appropriate appliances. In so far as the conditions are comparable, experience shows that this feat is not successfully accomplished in the case of the neuroses either. But I am aware that this argument is not unimpeachable. There is such a thing as a 'trigger-action'.

In the light of the knowledge we have gained from psycho-analysis we can describe the difference between hypnotic and psycho-analytic suggestion as follows. Hypnotic treatment seeks to cover up and gloss over something in mental life; analytic treatment seeks to expose and get rid of something. The former acts like a cosmetic, the latter like surgery. The former makes use of suggestion in order to forbid the symptoms; it strengthens the repressions, but, apart from that, leaves all the processes that have led to the formation of the symptoms unaltered. Analytic treatment makes its impact further back towards the roots, where the conflicts are which gave rise to the symptoms, and uses suggestion in order to alter the outcome of those conflicts. Hypnotic treatment leaves the patient inert and unchanged, and for that reason, too, equally unable to resist any fresh occasion for falling ill. An analytic treatment demands from both doctor and patient the accomplishment of serious work, which is employed in lifting internal resistances. Through the overcoming of these resistances the patient's mental life is permanently changed, is raised to a high level of development and remains protected against fresh possibilities of falling ill. This work of overcoming resistances is the essential function of analytic treatment; the patient has to accomplish it and the doctor makes this possible for him with the help of suggestion operating in an *educative* sense. For that reason psycho-analytic treatment has justly been described as a kind of *after-education*.

I hope I have now made it clear to you in what way our method of employing suggestion therapeutically differs from the only method possible in hypnotic treatment. You will understand too, from the fact that suggestion can be traced back to transference, the capriciousness which struck us in hypnotic therapy, while analytic treatment remains calculable within its limits. In using hypnosis we are dependent on the state of the patient's capacity for transference without being able to influence it itself. The transference of a person who is to be hypnotized may be negative or, as most frequently, ambivalent, or he may have protected himself against his transference by adopting special attitudes; of that we learn nothing. In psycho-analysis we act upon the transference itself, resolve what opposes it, adjust the instrument with which we wish to make our impact. Thus it becomes possible for us to derive an entirely fresh advantage from the power of suggestion; we get it into our hands. The patient does not suggest to himself whatever he pleases: we guide his suggestion so far as he is in any way accessible to its influence.

But you will now tell me that, no matter whether we call the motive force of our analysis transference or suggestion, there is a risk that the influencing of our patient may make the objective certainty of our findings doubtful. What is advantageous to our therapy is damaging to our researches. This is the objection that is most often raised against psycho-analysis, and it must be admitted that, though it is groundless, it cannot be rejected as unreasonable. If it were justified, psycho-analysis would be nothing more than a particularly well-disguised and particularly effective form of suggestive treatment and we should have to attach little weight to all that it tells us about what influences our lives, the dynamics of the mind or the unconscious. That is what our opponents believe; and in especial they think that we have 'talked' the patients into everything relating to the importance of sexual experiences - or even into those experiences themselves - after such notions have grown up in our own depraved imagination. These accusations are contradicted more easily by an appeal to experience than by the help of theory. Anyone who has himself carried out psycho-analyses will have been able to convince himself on countless occasions that it is impossible to make suggestions to a patient in that way. The doctor has no difficulty, of course, in making him a supporter of some particular theory and in thus making him share some possible error of his own. In this respect the patient is behaving like anyone else - like a pupil - but this only affects his intelligence, not his illness. After all, his conflicts will only be successfully solved and his resistances overcome if the anticipatory ideas he is given tally with what is real in him. Whatever in the doctor's conjectures is inaccurate drops out in the course of the analysis; it has to be withdrawn and replaced by something more correct. We endeavour by a careful technique to avoid the occurrence of premature successes due to suggestion; but no harm is done even if they do occur, for we are not satisfied by a first success. We do not regard an analysis as at an end until all the obscurities of the case are cleared up, the gaps in the patient's memory filled in, the precipitating causes of the repressions discovered. We look upon successes that set in too soon as obstacles rather than as a help to the work of analysis; and we put an end to such successes by constantly resolving the transference on which they are based. It is this last characteristic which is the fundamental distinction between analytic and purely suggestive therapy, and which frees the results of analysis from the suspicion of being successes due to suggestion. In every other kind of suggestive treatment the transference is carefully preserved and left untouched; in analysis it is itself subjected to treatment and is dissected in all the shapes in which it appears. At the end of an analytic treatment the transference must itself be cleared away; and if success is then obtained or continues, it rests, not on suggestion, but on the achievement by its means of an overcoming of internal resistances, on the internal change that has been brought about in the patient.

The acceptance of suggestions on individual points is no doubt discouraged by the fact that during the treatment we are struggling unceasingly against resistances which are able to transform themselves into negative (hostile) transferences. Nor must we fail to point out that a large number of the individual findings of analysis, which might otherwise be suspected to being products of suggestion, are confirmed from another and irreproachable source. Our guarantors in this case are the sufferers from dementia praecox and paranoia, who are of course far above any suspicion of being influenced by suggestion. The translations of symbols and the phantasies, which these patients produce for us and which in them have forced their way through into consciousness, coincide faithfully with the results of our investigations into the unconscious of transference neurotics and thus confirm the objective correctness of our interpretations, on which doubt is so often thrown. You will not, I think, be going astray if you trust analysis on these points.

I will now complete my picture of the mechanism of cure by clothing it in the formulas of the libido theory. A neurotic is incapable of enjoyment and of efficiency - the former because his libido is not directed on to any real object and the latter because he is obliged to employ a great deal of this available energy on keeping his libido under repression and on warding off its assaults. He would become healthy if the conflict between his ego and his libido came to an end and if his ego had his libido again at its disposal. The therapeutic task consists, therefore, in freeing the libido from its present attachments, which are withdrawn from the ego, and in making it once more serviceable to the ego. Where, then, is the neurotic's libido situated? It is easily found: it is attached to the symptoms, which yield it the only substitutive satisfaction possible at the time. We must therefore make ourselves masters of the symptoms and resolve them - which is precisely the same thing that the patient requires of us. In order to resolve the symptoms, we must go back as far as their origin, we must renew the conflict from which they arose, and, with the help of motive forces which were not at the patient's disposal in the past, we must guide it to a different outcome. This revision of the process of repression can be accomplished only in part in connection with the memory traces of the processes which led to repression. The decisive part of the work is achieved by creating in the patient's relation to the doctor - in the 'transference' - new editions of the old conflicts; in these the patient would like to behave in the same way as he did in the past, while we, by summoning up every available mental force, compel him to come to a fresh decision. Thus the transference becomes the battlefield on which all the mutually struggling forces should meet one another.

All the libido, as well as everything opposing it, is made to converge solely on the relation with the doctor. In this process the symptoms are inevitably divested of libido. In place of his patient's true illness there appears the artificially constructed transference illness, in place of the various unreal objects of the libido there appears a single, and once more imaginary, object in the person of the doctor. But, by the help of the doctor's suggestion, the new struggle around this object is lifted to the highest psychical level: it takes place as a normal mental conflict. Since a fresh repression is avoided, the alienation between ego and libido is brought to an end and the subject's mental unity is restored. When the libido is released once more from its temporary object in the person of the doctor, it cannot return to its earlier objects, but is at the disposal of the ego. The forces against which we have been struggling during our work of therapy are, on the one hand, the ego's antipathy to certain trends of the libido - an antipathy expressed in a tendency to repression - and, on the other hand, the tenacity or adhesiveness of the libido, which dislikes leaving objects that it has once cathected.

Thus our therapeutic work falls into two phases. In the first, all the libido is forced from the symptoms into the transference and concentrated there; in the second, the struggle is waged around this new object and the libido is liberated from it. The change which is decisive for a favourable outcome is the elimination of repression in this renewed conflict so that the libido cannot withdraw once more from the ego by flight into the unconscious. This is made possible by the alteration of the ego which is accomplished under the influence of the doctor's suggestion. By means of the work of interpretation, which transforms what is unconscious into what is conscious, the ego is enlarged at the cost of this unconscious; by means of instruction, it is made conciliatory towards the libido and inclined to grant it some satisfaction, and its repugnance to the claims of the libido is diminished by the possibility of disposing of a portion of it by sublimation. The more closely events in the treatment coincide with this ideal description, the greater will be the success of the psycho-analytic therapy. It finds its limits in the lack of mobility of the libido, which may refuse to leave its objects, and the rigidity of narcissism, which will not allow transference on to objects to increase beyond certain bounds. Further light may perhaps be thrown on the dynamics of the process of cure if I say that we get hold of the whole of the libido which has been withdrawn from the dominance of the ego by attracting a portion of it on to ourselves by means of the transference.

It will not be out of place to give a warning that we can draw no direct conclusion from the distribution of the libido during and resulting from the treatment as to how it was distributed during the illness. Suppose we succeeded in bringing a case to a favourable conclusion by setting up and then resolving a strong father-transference to the doctor. It would not be correct to conclude that the patient had suffered previously from a similar unconscious attachment of his libido to his father. His father-transference was merely the battlefield on which we gained control of his libido; the patient's libido as directed to it from other positions. A battlefield need not necessarily coincide with one of the enemy's key fortresses. The defence of a hostile capital need not take place just in front of its gates. Not until after the transference has once more been resolved can we reconstruct in our thoughts the distribution of the libido which had prevailed during the illness.

From the standpoint of the libido theory, too, we may say a last word on dreams. A neurotic's dreams help us, like his parapraxes and his free associations to them, to discover the sense of his symptoms and to reveal the way in which his libido is allocated. They show us, in the form of a wish-fulfilment, what wishful impulses have been subjected to repression and to what objects the libido withdrawn from the ego has become attached. For this reason the interpretation of dreams plays a large part in a psycho-analytic treatment, and in some cases it is over long periods the most important instrument of our work. We already know that the state of sleep in itself leads to a certain relaxation of the repressions. A repressed impulse, owing to this reduction in the pressure weighing down upon it, becomes able to express itself far more clearly in a dream than it can be allowed to be expressed by a symptom during the day. The study of dreams therefore becomes the most convenient means of access to a knowledge of the repressed unconscious, of which the libido withdrawn from the ego forms a part.

But the dreams of neurotics do not differ in any important respect from those of normal people; it is possible, indeed, that they cannot be distinguished from them at all. It would be absurd to give an account of the dreams of neurotics which could not also apply to the dreams of normal people. We must therefore say that the difference between neurosis and health holds only during the day; it is not prolonged into dream-life. We are obliged to carry over to healthy people a number of hypotheses which arise in connection with neurotics as a result of the link between the latter's dreams and their symptoms. We cannot deny that healthy people as well possess in their mental life what alone makes possible the formation both of dreams and of symptoms, and we must conclude that they too have carried out repressions, that they expend a certain amount of energy in order to maintain them, that their unconscious system conceals repressed impulses which are still cathected with energy, and that *a portion of their libido is withdrawn from their ego's disposal*. Thus a healthy person, too, is virtually a neurotic; but dreams appear to be the only symptoms which he is capable of forming. It is true that if one subjects his waking life to a closer examination one discovers something that contradicts this appearance - namely that this ostensibly healthy life is interspersed with a great number of trivial and in practice unimportant symptoms.

The distinction between nervous health and neurosis is thus reduced to a practical question and is decided by the outcome - by whether the subject is left with a sufficient amount of capacity for enjoyment and of efficiency. It probably goes back to the relative sizes of the quota of energy that remains free and of that which is bound by repression, and is of a quantitative not of a qualitative nature. I need not tell you that this discovery is the theoretical justification for our conviction that neuroses are in principle curable in spite of their being based on constitutional disposition.

The identity of the dreams of healthy and neurotic people enables us to infer thus much in regard to defining the characteristics of health. But in regard to dreams themselves we can make a further inference: we must not detach them from their connection with neurotic symptoms, we must not suppose that their essential nature is exhausted by the formula that describes them as a translation of thoughts into an archaic form of expression, but we must suppose that they exhibit to us allocations of the libido and object-cathexes that are really present.

We shall soon have reached the end. You are perhaps disappointed that on the topic of the psycho-analytic method of therapy I have only spoken to you about theory and not about the conditions which determine whether a treatment is to be undertaken or about the results it produces. I shall discuss neither: the former because it is not my intention to give you practical instructions on how to carry out a psycho-analysis, and the latter because several reasons deter me from it. At the beginning of our talks, I emphasized the fact that under favourable conditions we achieve successes which are second to none of the finest in the field of internal medicine; and I can now add something further - namely that they could not have been achieved by any other procedure. If I were to say more than this I should be suspected of trying to drown the loudly raised voices of depreciation by self-advertisement. The threat has repeatedly been made against psycho-analysts by our medical 'colleagues' - even at public congresses - that a collection of the failures and damaging results of analysis would be published which would open the suffering public's eyes to the worthlessness of this method of treatment. But, apart from the malicious, denunciatory character of such a measure, it would not even be calculated to make it possible to form a correct judgement of the therapeutic effectiveness of analysis. Analytic therapy, as you know, is in its youth; it has taken a long time to establish its technique, and that could only be done in the course of working and under the influence of increasing experience. In consequence of the difficulties in giving instruction, the doctor who is a beginner in psycho-analysis is thrown back to a greater extent than other specialists on his own capacity for further development, and the results of his first years will never make it possible to judge the efficacy of analytic therapy.

Many attempts at treatment miscarried during the early period of analysis because they were undertaken in cases which were altogether unsuited to the procedure and which we should exclude to-day on the basis of our present view of the indications for treatment. But these indications, too, could only be arrived at by experiment. In those days we did not know *a priori* that paranoia and dementia praecox in strongly marked forms are inaccessible, and we had a right to make trial of the method on all kinds of disorders. But most of the failures of those early years were due not to the doctor's fault or an unsuitable choice of patients but to unfavourable external conditions. Here we have only dealt with internal resistances, those of the patient, which are inevitable and can be overcome. The external resistances which arise from the patient's circumstances, from his environment, are of small theoretical interest but of the greatest practical importance. Psycho-analytic treatment may be compared with a surgical operation and may similarly claim to be carried out under arrangements that will be the most favourable for its success. You know the precautionary measures adopted by a surgeon: a suitable room, good lighting, assistants, exclusion of the patient's relatives, and so on. Ask yourselves now how many of these operations would turn out successfully if they had to take place in the presence of all the members of the patient's family, who would stick their noses into the field of the operation and exclaim aloud at every incision. In psycho-analytic treatments the intervention of relatives is a positive danger and a danger one does not know how to meet. One is armed against the patient's internal resistances which one knows are inevitable, but how can one ward off these external resistances? No kind of explanations make any impression on the patient's relatives; they cannot be induced to keep at a distance from the whole business, and one cannot make common cause with them because of the risk of losing the confidence of the patient, who - quite rightly moreover - expects the person in whom he has put his trust to take his side. No one who has any experience of the rifts which so often divide a family will, if he is an analyst, be surprised to find that the patient's closest relatives sometimes betray less interest in his recovering than in his remaining as he is. When, as so often, the neurosis is related to conflicts between members of a family, the healthy party will not hesitate long in choosing between his own interest and the sick party's recovery. It is not to be wondered at, indeed, if a husband looks with disfavour on a treatment in which, as he may rightly suspect, the whole catalogue of his sins will be brought to light. Nor do we wonder at it; but we cannot in that case blame ourselves if our efforts remain unsuccessful and the treatment is broken off prematurely because the husband's resistance is added to that of his sick wife. We had in fact undertaken something which in the prevailing circumstances was unrealizable.

Instead of reporting a number of cases, I will tell you the story of a single one, in which, from considerations of medical discretion, I was condemned to play a long-suffering part. I undertook the analytic treatment - it was many years ago - of a girl who had for some time been unable, owing to anxiety, to go out in the street or to stay at home by herself. The patient slowly brought out an admission that her imagination had been seized by chance observations of the affectionate relations between her mother and a well-to-do friend of the family. But she was so clumsy - or so subtle - that she gave her mother a hint of what was being talked about in the analytic sessions. She brought this about by changing her behaviour towards her mother, by insisting on being protected by no one but her mother from her anxiety at being alone and by barring the door to her in her anxiety if she tried to leave the house. Her mother had herself been very neurotic in the past, but had been cured years before in a hydropathic establishment. Or rather, she had there made the acquaintance of the man with whom she was able to enter into a relation that was in every way satisfying to her. The girl's passionate demands took her aback, and she suddenly understood the meaning of her daughter's anxiety: the girl had made herself ill in order to keep her mother prisoner and to rob her of the freedom of movement that her relations with her lover required. The mother quickly made up her mind and brought the obnoxious treatment to an end. The girl was taken to a sanatorium for nervous diseases and was demonstrated for many years as 'a poor victim of psycho-analysis'. All this time, too, I was pursued by the calumny of responsibility for the unhappy end of the treatment. I kept silence, for I thought I was bound by the duty of medical discretion. Long afterwards I learnt from one of my colleagues, who visited the sanatorium and had seen the agoraphobic girl there, that the *liaison* between her mother and the well-to-do friend of the family was common knowledge in the city and that it was probably connived at by the husband and father. Thus it was to this 'secret' that the treatment had been sacrificed.

In the years before the war, when arrivals from many foreign countries made me independent of the favour or disfavour of my own city, I followed a rule of not taking on patient for treatment unless he was *sui juris*, not dependent on anyone else in the essential relations of his life. This is not possible, however, for every psycho-analyst. Perhaps you may conclude from my warning against relatives that patients designed for psycho-analysis should be removed from their families and that this kind of treatment should accordingly be restricted to inmates of hospitals for nervous diseases. I could not,, however, follow you in that. It is much more advantageous for patients, (in so far as they are not in a phase of severe exhaustion) to remain during the treatment in the conditions in which they have to struggle with the tasks that face them. But the patients' relatives ought not to cancel out this advantage by their conduct and should not offer any hostile opposition to the doctor's efforts. But how do you propose to influence in that direction factors like these which are inaccessible to us? And you will guess, of course, how much the prospects of a treatment are determined by the patient's social *milieu* and the cultural level of his family.

This presents a gloomy prospect for the effectiveness of psycho-analysis as a therapy - does it not? - even though we are able to explain the great majority of our failures by attributing them to interfering external factors. Friends of analysis have advised us to meet the threatened publication of our failures with statistics of our successes drawn up by ourselves. I did not agree to this. I pointed out that statistics are worthless if the items assembled in them are too heterogeneous; and the cases of neurotic illness which we had taken into treatment were in fact incomparable in a great variety of respects. Moreover, the period of time that could be covered was too short to make it possible to judge the durability of the cures. And it was altogether impossible to report on many of the cases: they concerned people who had kept both their illness and its treatment secret, and their recovery had equally to be kept secret. But the strongest reason for holding back lay in the realization that in matters of therapy people behave highly irrationally, so that one has no prospect of accomplishing anything with them by rational means. A therapeutic novelty is either received with delirious enthusiasm - as, for instance, when Koch introduced his first tuberculin against tuberculosis to the public - or it is treated with abysmal distrust - like Jenner's vaccination, which was in fact a blessing and which even to-day has its irreconcilable opponents. There was obviously a prejudice against psycho-analysis. If one had cured a severe case, one might hear people say: 'That proves nothing. He would have recovered on his own account by this time.' And when a woman patient, who had already passed through four cycles of depression and mania, came to be treated by me during an interval after an attack of melancholia and three weeks later started on a phase of mania, all the members of her family and a high medical authority, too, who was called in for consultation - were convinced that the fresh attack could only be the result of my attempted analysis. Nothing can be done against prejudices. You can see it again to-day in the prejudices which each group of nations at war has developed against the other. The most sensible thing to do is to wait, and to leave such prejudices to the eroding effects of time. One day the same people begin to think about the same things in quite a different way from before; why they did not think so earlier remains a dark mystery.

It is possible that the prejudice against analytic treatment is already diminishing. The constant spread of analytic teachings, the increasing number of doctors practising analysis in a number of countries seems to vouch for this. When I was a young doctor, I found myself in a similar storm of indignation on the doctors' part against treatment by hypnotic suggestion, which is now held up in contrast to analysis by people of 'moderate' views. Hypnotism, however, has not fulfilled its original promise as a therapeutic agent. We psycho-analysts may claim to be its legitimate heirs and we do not forget how much encouragement and theoretical clarification we owe to it. The damaging results attributed to psycho-analysis are restricted essentially to passing manifestations of increased conflict if an analysis is clumsily carried out or if it is broken off in the middle. You have heard an account of what we do with our patients and can form your own judgement as to whether our efforts are calculated to lead to any lasting damage. Abuse of analysis is possible in various directions; in particular, the transference is a dangerous instrument in the hands of an unconscientious doctor. But no medical instrument or procedure is guaranteed against abuse; if a knife does not cut, it cannot be used for healing either.

I have finished, Ladies and Gentlemen. It is more than a conventional form of words if I admit that I myself am profoundly aware of the many defects in the lectures I have given you. I regret above all that I have so often promised to return later to a topic I have lightly touched on and have then found no opportunity of redeeming my promise. I undertook to give you an account of a subject which is still incomplete and in process of development, and my condensed summary has itself turned out to be an incomplete one. At some points I have set out the material on which to draw a conclusion and have then myself not drawn it. But I could not pretend to make you into experts; I have only tried to stimulate and enlighten you.

FROM THE HISTORY OF AN INFANTILE NEUROSIS
(1918 [1914])

Intentionally left blank

FROM THE HISTORY OF AN INFANTILE NEUROSIS ¹

I

INTRODUCTORY REMARKS

The case upon which I propose to report in the following pages (once again only in a fragmentary manner) is characterized by a number of peculiarities which require to be emphasized before I proceed to a description of the facts themselves. It is concerned with a young man whose health had broken down in his eighteenth year after a gonorrhoeal infection, and who was entirely incapacitated and completely dependent upon other people when he began his psycho-analytic treatment several years later. He had lived an approximately normal life during the ten years of his boyhood that preceded the date of his illness, and got through his studies at his secondary school without much trouble. But his earlier years were dominated by a severe neurotic disturbance, which began immediately before his fourth birthday as an anxiety-hysteria (in the shape of an animal phobia), then changed into an obsessional neurosis with a religious content, and lasted with its offshoots as far as into his tenth year.

¹ This case history was written down shortly after the termination of the treatment, in the winter of 1914-15. At that time I was still freshly under the impression of the twisted re-interpretations which C. G. Jung and Alfred Adler were endeavouring to give to the findings of psycho-analysis. This paper is therefore connected with my essay 'On the History of the Psycho-Analytic Movement' which was published in the *Jahrbuch der Psychoanalyse* in 1914. It supplements the polemic contained in that essay, which is in its essence of a personal character, by an objective estimation of the analytic material. It was originally intended for the next volume of the *Jahrbuch*, the appearance of which was, however, postponed indefinitely owing to the obstacles raised by the Great War. I therefore decided to add it to the present collection of papers which was being issued by a new publisher. Meanwhile I had been obliged to deal in my *Introductory Lectures on Psycho-Analysis* (which I delivered in 1916 and 1917) with many points which should have been raised for the first time in this paper. No alterations of any importance have been made in the text of the first draft; additions are indicated by means of square brackets.

Only this infantile neurosis will be the subject of my communication. In spite of the patient's direct request, I have abstained from writing a complete history of his illness, of his treatment, and of his recovery, because I recognized that such a task was technically impracticable and socially impermissible. This at the same time removes the possibility of demonstrating the connection between his illness in childhood and his later and permanent one. As regards the latter I can only say that on account of it the patient spent a long time in German sanatoria, and was at that period classified in the most authoritative quarters as a case of 'manic-depressive insanity'. This diagnosis was certainly applicable to the patient's father, whose life with its wealth of activity and interests, was disturbed by repeated attacks of severe depression. But in the son I was never able, during an observation which lasted several years, to detect any changes of mood which were disproportionate to the manifest psychological situation either in their intensity or in the circumstances of their appearance. I have formed the opinion that this case, like many others which clinical psychiatry has labelled with the most multifarious and shifting diagnoses, is to be regarded as a condition following on an obsessional neurosis which has come to an end spontaneously, but has left a defect behind it after recovery.

My description will therefore deal with an infantile neurosis which was analysed not while it actually existed, but only fifteen years after its termination. This state of things has its advantages as well as its disadvantages in comparison with the alternative. An analysis which is conducted upon a neurotic child itself must, as a matter of course, appear to be more trustworthy, but it cannot be very rich in material; too many words and thoughts have to be lent to the child, and even so the deepest strata may turn out to be impenetrable to consciousness. An analysis of a childhood disorder through the medium of recollection in an intellectually mature adult is free from these limitations; but it necessitates our taking into account the distortion and refurbishing to which a person's own past is subjected when it is looked back upon from a later period. The first alternative perhaps gives the more convincing results; the second is by far the more instructive.

In any case it may be maintained that analysis of children's neuroses can claim to possess a specially high theoretical interest. They afford us, roughly speaking, as much help towards a proper understanding of the neuroses of adults as do children's dreams in respect to the dreams of adults. Not, indeed, that they are more perspicuous or poorer in elements; in fact, the difficulty of feeling one's way into the mental life of a child makes them set the physician a particularly difficult task. But nevertheless, so many of the later deposits are wanting in them that the essence of the neurosis springs to the eyes with unmistakable distinctness. In the present phase of the battle which is raging round psycho-analysis the resistance to its findings has, as we know, taken on a new form. People were content formerly to dispute the reality of the facts which are asserted by analysis; and for this purpose the best technique seemed to be to avoid examining them. That procedure appears to be slowly exhausting itself; and people are now adopting another plan of recognizing the facts, but of eliminating, by means of twisted interpretations, the consequences that follow from them, so that the critics can still ward off the objectionable novelties as efficiently as ever. The study of children's neuroses exposes the complete inadequacy of these shallow or high-handed attempts at re-interpretation. It shows the predominant part that is played in the formation of neuroses by those libidinal motive forces which are so eagerly disavowed, and reveals the absence of any aspirations towards remote cultural aims, of which the child still knows nothing, and which cannot therefore be of any significance for him.

Another characteristic which makes the present analysis noteworthy is connected with the severity of the illness and the duration of the treatment. Analyses which lead to a favourable conclusion in a short time are of value in ministering to the therapist's self-esteem and substantiate the medical importance of psycho-analysis; but they remain for the most part insignificant as regards the advancement of scientific knowledge. Nothing new is learnt from them. In fact they only succeed so quickly because everything that was necessary for their accomplishment was already known. Something new can only be gained from analyses that present special difficulties, and to the overcoming of these a great deal of time has to be devoted. Only in such cases do we succeed in descending into the deepest and most primitive strata of mental development and in gaining from there solutions for the problems of the later formations. And we feel afterwards that, strictly speaking, only an analysis which has penetrated so far deserves the name. Naturally a single case does not give us all the information that we should like to have. Or, to put it more correctly, it might teach us everything, if we were only in a position to make everything out, and if we were not compelled by the inexperience of our own perception to content ourselves with a little.

As regards these fertile difficulties the case I am about to discuss left nothing to be desired. The first years of the treatment produced scarcely any change. Owing to a fortunate concatenation, all the external circumstances nevertheless combined to make it possible to proceed with the therapeutic experiment. I can easily believe that in less favourable circumstances the treatment would have been given up after a short time. Of the physician's point of view I can only declare that in a case of this kind he must behave as 'timelessly' as the unconscious itself, if he wishes to learn anything or to achieve anything. And in the end he will succeed in doing so, if he has the strength to renounce any short-sighted therapeutic ambition. It is not to be expected that the amount of patience, adaptability, insight, and confidence demanded of the patient and his relatives will be forthcoming in many other cases. But the analyst has a right to feel that the results which he has attained from such lengthy work in one case will help substantially to reduce the length of the treatment in a subsequent case of equal severity, and that by submitting on a single occasion

The patient with whom I am here concerned remained for a long time unassailably entrenched behind an attitude of 'obliging apathy'. He listened, understood, and remained unapproachable. His unimpeachable intelligence was, as it were, cut off from the instinctual forces which governed his behaviour in the few relations of life that remained to him. It required a long education to induce him to take an independent share in the work; and when as a result of this exertion he began for the first time to feel relief, he immediately gave up working in order to avoid any further changes, and in order to remain comfortably in the situation which had been thus established. His shrinking from a self-sufficient existence was so great as to outweigh all the vexations of his illness. Only one way was to be found of overcoming it. I was obliged to wait until his attachment to myself had become strong enough to counter-balance this shrinking, and then played off this one factor against the other. I determined - but not until trustworthy signs had led me to judge that the right moment had come that the treatment must be brought to an end at a particular fixed date, no matter how far it had advanced. I was resolved to keep to the date; and eventually the patient came to see that I was in earnest. Under the inexorable pressure of this fixed limit his resistance and his fixation to the illness gave way, and now in a disproportionately short time the analysis produced all the material which made it possible to clear up his inhibitions and remove his symptoms. All the information, too, which enabled me to understand his infantile neurosis is derived from this last period of the work, during which resistance temporarily disappeared and the patient gave an impression of lucidity which is usually attainable only in hypnosis.

Thus the course of this treatment illustrates a maxim whose truth has long been appreciated in the technique of analysis. The length of the road over which an analysis must travel with the patient, and the quantity of material which must be mastered on the way, are of no importance in comparison with the resistance which is met with in the course of the work, and are only of importance at all in so far as they are necessarily proportional to the resistance. The situation is the same as when to-day an enemy army needs weeks and months to make its way across a stretch of country which in times of peace was traversed by an express train in a few hours and which only a short time before had been passed over by the defending army in a few days.

A third peculiarity of the analysis which is to be described in these pages has only increased my difficulty in deciding to make a report upon it. On the whole its results have coincided in the most satisfactory manner with our previous knowledge, or have been easily embodied into it. Many details, however, seemed to me myself to be so extraordinary and incredible that I felt some hesitation in asking other people to believe them. I requested the patient to make the strictest criticism of his recollections, but he found nothing improbable in his statements and adhered closely to them. Readers may at all events rest assured that I myself am only reporting what I came upon as an independent experience, uninfluenced by my expectation. So that there was nothing left for me but to remember the wise saying that there are more things in heaven and earth than are dreamed of in our philosophy. Anyone who could succeed in eliminating his pre-existing convictions even more thoroughly could no doubt discover even more such things.

II

GENERAL SURVEY OF THE PATIENT'S ENVIRONMENT
AND OF THE HISTORY OF THE CASE

I am unable to give either a purely historical or a purely thematic account of my patient's story; I can write a history neither of the treatment nor of the illness, but I shall find myself obliged to combine the two methods of presentation. It is well known that no means has been found of in any way introducing into the reproduction of an analysis the sense of conviction which results from the analysis itself. Exhaustive verbatim reports of the proceedings during the hours of analysis would certainly be of no help at all; and in any case the technique of the treatment makes it impossible to draw them up. So analyses such as this are not published in order to produce conviction in the minds of those whose attitude has hitherto been recusant and sceptical. The intention is only to bring forward some new facts for investigators who have already been convinced by their own clinical experiences.

I shall begin, then, by giving a picture of the child's world, and by telling as much of the story of his childhood as could be learnt without any exertion; it was not, indeed, for several years that the story became any less incomplete and obscure.

His parents had been married young, and were still leading a happy married life, upon which their ill-health was soon to throw the first shadows. His mother began to suffer from abdominal disorders, and his father from his first attacks of depression, which led to his absence from home. Naturally the patient only came to understand his father's illness very much later on, but he was aware of his mother's weak health even in his early childhood. As a consequence of it she had relatively little to do with the children. One day, certainly before his fourth year, while his mother was seeing off the doctor to the station and he himself was walking beside her, holding her hand, he overheard her lamenting her condition. Her words made a deep impression upon him, and later on he applied them to himself. He was not the only child; he had a sister, about two years his elder, lively, gifted, and precociously naughty, who was to play an important part in his life.

As far back as he could remember he was looked after by a nurse, an uneducated old woman of peasant birth, with an untiring affection for him. He served her as a substitute for a son of her own who had died young. The family lived on a country estate, from which they used to move to another for the summer. The two estates were not far from a large town. There was a break in his childhood when his parents sold the estates and moved into the town. Near relatives used often to pay them long visits upon one estate or the other - brothers of his father, sisters of his mother and their children, and his grandparents on his mother's side. During the summer his parents used to be away for a few weeks. In a screen memory he saw himself with his nurse looking after the carriage which was driving off with his father, mother and sister, and then going peaceably back into the house. He must have been very small at that time.¹ Next summer his sister was left at home, and an English governess was engaged, who became responsible for the supervision of the children.

In his later years he was told many stories about his childhood.² He knew a great deal himself, but it was naturally disconnected both as regards date and subject-matter. One of these traditions, which was repeated over and over again in his presence on the occasion of his later illness, introduces us to the problem with whose solution we shall be occupied. He seems at first to have been a very good-natured, tractable, and even quiet child, so that they used to say of him that he ought to have been the girl and his elder sister the boy. But once, when his parents came back from their summer holiday, they found him transformed. He had become discontented, irritable and violent, took offence on every possible occasion, and then flew into a rage and screamed like a savage; so that, when this state of things continued, his parents expressed their misgivings as to whether it would be possible to send him to school later on. This happened during the summer while the English governess was with them. She turned out to be an eccentric and quarrelsome person, and, moreover, to be addicted to drink. The boy's mother was therefore inclined to ascribe the alteration in his character to the influence of this Englishwoman, and assumed that she had irritated him by her treatment. His sharp-sighted grandmother, who had spent the summer with the children, was of opinion that the boy's irritability had been provoked by the dissensions between the Englishwoman and the nurse. The Englishwoman had repeatedly called the nurse a witch, and had obliged her to leave the room; the little boy had openly taken the side of his beloved 'Nanya' and let the governess see his hatred. However it may have been, the Englishwoman was sent away soon after the parents' return, without there being any consequent change in the child's unbearable behaviour.

¹ Two and a half years old. It was possible later on to determine almost all the dates with certainty.

² Information of this kind may, as a rule, be employed as absolutely authentic material. So it may seem tempting to take the easy course of filling up the gaps in a patient's memory by making enquiries from the older members of his family; but I cannot advise too strongly against such a technique. Any stories that may be told by relatives in reply to enquiries and requests are at the mercy of every critical misgiving that can come into play. One invariably regrets having made oneself dependent upon such information; at the same time confidence in the analysis is shaken and a court of appeal is set up over it. Whatever can be remembered at all will anyhow come to light in the further course of analysis.

The patient had preserved his memory of this naughty period. According to his belief he made the first of his scenes one Christmas, when he was not given a double quantity of presents - which were his due, because Christmas Day was at the same time his birthday. He did not spare even his beloved Nanya with his importunity and touchiness, and even tormented her more remorselessly perhaps than anyone. But the phase which brought with it his change in character was inextricably connected in his memory with many other strange and pathological phenomena which he was unable to arrange in chronological sequence. He threw all the incidents that I am now about to relate (which cannot possibly have been contemporaneous, and which are full of internal contradictions) into one and the same period of time, to which he gave the name 'still on the first estate'. He thought they must have left that estate by the time he was five years old. Thus he could recollect how he had suffered from a fear, which his sister exploited for the purpose of tormenting him. There was a particular picture-book, in which a wolf was represented, standing upright and striding along. Whenever he caught sight of this picture he began to scream like a lunatic that he was afraid of the wolf coming and eating him up. His sister, however, always succeeded in arranging so that he was obliged to see this picture, and was delighted at his terror. Meanwhile he was also frightened at other animals as well, big and little. Once he was running after a beautiful big butterfly, with striped yellow wings which ended in points, in the hope of catching it. (It was no doubt a 'swallow-tail') He was suddenly seized with a terrible fear of the creature, and, screaming, gave up the chase. He also felt fear and loathing of beetles and caterpillars. Yet he could also remember that at this very time he used to torment beetles and cut caterpillars to pieces. Horses, too, gave him an uncanny feeling. If a horse was beaten he began to scream, and he was once obliged to leave a circus on that account. On other occasions he himself enjoyed beating horses. Whether these contradictory sorts of attitudes towards animals were really in operation simultaneously, or whether they did not more probably replace one another, but if so in what order and when - to all these questions his memory could offer no decisive reply. He was also unable to say whether his naughty period was *replaced* by a phase of illness or whether it persisted right through the latter. But, in any case, the statements of his that follow justified the assumption that during these years of his childhood he went through an easily recognizable attack of obsessional neurosis. He related how during a long period he was very pious. Before he went to sleep he was obliged to pray for a long time and to make an endless series of signs of the cross. In the evening, too, he used to make the round of all the holy pictures that hung in the room, taking a chair with him, upon which he climbed, and used to kiss each one of them devoutly. It was utterly inconsistent with this pious ceremonial - or, on the other hand, perhaps it was quite consistent with it - that he should recollect some blasphemous thoughts which used to come into his head like an inspiration from the devil. He was obliged to think 'God-swine' or 'God-shit'. Once while he was on a journey to a health resort in Germany he was tormented by the obsession of having to think of the Holy Trinity whenever he saw three heaps of horse-dung or other excrement lying in the road. At that time he used to carry out another peculiar ceremonial when he saw people that he felt sorry for, such as beggars, cripples, or very old men. He had to breathe out noisily, so as not to become like them; and under certain conditions he had to draw in his breath vigorously. I naturally assumed that these obvious symptoms of an obsessional neurosis belonged to a somewhat later time and stage of development than the signs of anxiety and the cruel treatment of animals.

The patient's maturer years were marked by a very unsatisfactory relation to his father, who, after repeated attacks of depression, was no longer able to conceal the pathological features of his character. In the earliest years of the patient's childhood this relation had been a very affectionate one, and the recollection of it had remained in his memory. His father was very fond of him, and liked playing with him. From an early age he was proud of his father, and was always declaring that he would like to be a gentleman like him. His Nanya told him that his sister was his mother's child, but that he was his father's - which had very much pleased him. Towards the end of his childhood there was an estrangement between him and his father. His father had an unmistakable preference for his sister, and he felt very much slighted by this. Later on fear of his father became the dominating factor.

All of the phenomena which the patient associated with the phase of his life that began with his naughtiness disappeared in about his eighth year. They did not disappear at a single blow, and made occasional reappearances, but finally gave way, in the patient's opinion, before the influence of the masters and tutors, who then took the place of the women who had hitherto looked after him. Here, then, in the briefest outline, are the riddles for which the analysis had to find a solution. What was the origin of the sudden change in the boy's character? What was the significance of his phobia and of his perversities? How did he arrive at his obsessive piety? And how are all these phenomena interrelated? I will once more recall the fact that our therapeutic work was concerned with a subsequent and recent neurotic illness, and that light could only be thrown upon these earlier problems when the course of the analysis led away for a time from the present, and forced us to make a *détour* through the prehistoric period of childhood.

III

THE SEDUCTION AND ITS IMMEDIATE CONSEQUENCES

It is easy to understand that the first suspicion fell upon the English governess, for the change in the boy made its appearance while she was there. Two screen memories had persisted, which were incomprehensible in themselves, and which related to her. On one occasion, as she was walking along in front of them, she said: 'Do look at my little tail!' Another time, when they were on a drive, her hat flew away, to the two children's great satisfaction. This pointed to the castration complex, and might permit of a construction being made to the effect that a threat uttered by her against the boy had been largely responsible for originating his abnormal conduct. There is no danger at all in communicating constructions of this kind to the person under analysis; they never do any damage to the analysis if they are mistaken; but at the same time they are not put forward unless there is some prospect of reaching a nearer approximation to the truth by means of them. The first effect of this supposition was the appearance of some dreams, which it was not possible to interpret completely, but all of which seemed to centre around the same material. As far as they could be understood, they were concerned with aggressive actions on the boy's part against his sister or against the governess and with energetic reproofs and punishments of account of them. It was as though . . . after her bath . . . he had tried . . . to undress his sister . . . to tear off her coverings . . . or veils - and so on. But it was not possible to get at any firm content from the interpretation; and since these dreams gave an impression of always working over the same material in various different ways, the correct reading of these ostensible reminiscences became assured: it could only be a question of phantasies, which the dreamer had made on the subject of his childhood at some time or other, probably at the age of puberty, and which had now come to the surface again in this unrecognizable form.

The explanation came at a single blow, when the patient suddenly called to mind the fact that, when he was still very small, 'on the first estate', his sister had seduced him into sexual practices. First came a recollection that in the lavatory, which the children used frequently to visit together, she had made this proposal: 'Let's show our bottoms', and had proceeded from words to deeds. Subsequently the more essential part of the seduction came to light, with full particulars as to time and place. It was in spring, at a time when his father was away; the children were in one room playing on the floor, while their mother was working in the next. His sister had taken hold of his penis and played with it, at the same time telling him incomprehensible stories about his Nanya, as though by way of explanation. His Nanya, she said, used to do the same thing with all kinds of people - for instance, with the gardener: she used to stand him on his head, and then take hold of his genitals.

Here, then, was the explanation of the phantasies whose existence we had already divined. They were meant to efface the memory of an event which later on seemed offensive to the patient's masculine self-esteem, and they reached this end by putting an imaginary and desirable converse in the place of the historical truth. According to these phantasies it was not he who had played the passive part towards his sister; but, on the contrary, he had been aggressive, had tried to see his sister undressed, had been rejected and punished, and had for that reason got into the rage which the family tradition talked of so much. It was also appropriate to weave the governess into this imaginative composition, since the chief responsibility for his fits of rage had been ascribed to her by his mother and grandmother. These phantasies, therefore, corresponded exactly to the legends by means of which a nation that has become great and proud tries to conceal the insignificance and failure of its beginnings.

The governess can actually have had only a very remote share in the seduction and its consequences. The scenes with his sister took place in the early part of the same year in which, at the height of the summer, the Englishwoman arrived to take the place of his absent parents. The boy's hostility to the governess came about, rather, in another way. By abusing the nurse and slandering her as a witch, she was in his eyes following in the footsteps of his sister, who had first told him such monstrous stories about the nurse; and in this way she enabled him to express openly against herself the aversion which, as we shall hear, he had developed against his sister as a result of his seduction.

But his seduction by his sister was certainly not a phantasy. Its credibility was increased by some information which had never been forgotten and which dated from a later part of his life, when he was grown up. A cousin who was more than ten years his elder told him in a conversation about his sister that he very well remembered what a forward and sensual little thing she had been: once, when she was a child of four or five, she had sat on his lap and opened his trousers to take hold of his penis.

I should like at this point to break off the story of my patient's childhood and say something of this sister, of her development and later fortunes, and of the influence she had on him. She was two years older than he was, and had always remained ahead of him. As a child she was boyish and unmanageable, but she then entered upon a brilliant intellectual development and distinguished herself by her acute and realistic powers of mind; she inclined in her studies to the natural sciences, but also produced imaginative writings of which her father had a high opinion. She was mentally far superior to her numerous early admirers, and used to make jokes at their expense. In her early twenties, however, she began to be depressed, complained that she was not good-looking enough, and withdrew from all society. She was sent to travel in the company of an acquaintance, an elderly lady, and after her return told a number of most improbable stories of how she had been ill-treated by her companion, but remained with her affections obviously fixed upon her alleged tormentor. While she was on a second journey, soon afterwards, she poisoned herself and died far away from her home. Her disorder is probably to be regarded as the beginning of a dementia praecox. She was one of the proofs of the conspicuously neuropathic heredity in her family, but by no means the only one. An uncle, her father's brother, died after long years of life as an eccentric, with indications pointing to the presence of a severe obsessional neurosis; while a good number of collateral relatives were and are afflicted with less serious nervous complaints.

Independently of the question of seduction, our patient, while he was a child, found in his sister an inconvenient competitor for the good opinion of his parents, and he felt very much oppressed by her merciless display of superiority. Later on he especially envied her the respect which his father showed for her mental capacity and intellectual achievements, while he, intellectually inhibited as he was since his obsessional neurosis, had to be content with a lower estimation. From his fourteenth year onwards the relations between the brother and sister began to improve; a similar disposition of mind and a common opposition to their parents brought them so close together that they got on with each other like the best of friends. During the tempestuous sexual excitement of his puberty he ventured upon an attempt at an intimate physical approach. She rejected him with equal decision and dexterity, and he at once turned away from her to a little peasant girl who was a servant in the house and had the same name as his sister. In doing so he was taking a step which had a determinant influence on his heterosexual choice of object, for all the girls with whom he subsequently fell in love - often with the clearest indications of compulsion - were also servants, whose education and intelligence were necessarily far inferior to his own. If all of these objects of his love were substitutes for the figure of the sister whom he had to forgo, then it could not be denied that an intention of debasing his sister and of putting an end to her intellectual superiority, which he had formerly found so oppressive, had obtained the decisive control over his object-choice.

Human sexual conduct, as well as everything else, has been subordinated by Alfred Adler to motive forces of this kind, which spring from the will to power, from the individual's self-assertive instinct. Without ever denying the importance of these motives of power and prerogative, I have never been convinced that they play the dominating and exclusive part that has been ascribed to them. If I had not pursued my patient's analysis to the end, I should have been obliged, on account of my observation of this case, to correct my preconceived opinion in a direction favourable to Adler. The conclusion of the analysis unexpectedly brought up new material which, on the contrary, showed that these motives of power (in this case the intention to debase) had determined the object-choice only in the sense of serving as a contributory cause and as a rationalization, whereas the true underlying determination enabled me to maintain my former convictions.¹

¹ See below, [p. 3575](#).

When the news of his sister's death arrived, so the patient told me, he felt hardly a trace of grief. He had to force himself to show signs of sorrow, and was able quite coolly to rejoice at having now become the sole heir to the property. He had already been suffering from his recent illness for several years when this occurred. But I must confess that this one piece of information made me for a long time uncertain in my diagnostic judgement of the case. It was to be assumed, no doubt, that his grief over the loss of the most dearly loved member of his family would meet with an inhibition in its expression, as a result of the continued operation of his jealousy of her and of the added presence of his incestuous love for her which had now become unconscious. But I could not do without some substitute for the missing outbursts of grief. And this was at last found in another expression of feeling which had remained inexplicable to the patient. A few months after his sister's death he himself made a journey in the neighbourhood in which she had died. There he sought out the burial-place of a great poet, who was at that time his ideal, and shed bitter tears upon his grave. This reaction seemed strange to him himself, for he knew that more than two generations had passed by since the death of the poet he admired. He only understood it when he remembered that his father had been in the habit of comparing his dead sister's works with the great poet's. He gave me another indication of the correct way of interpreting the homage which he ostensibly paid to the poet, by a mistake in his story which I was able to detect at this point. He had repeatedly specified before that his sister had shot herself; but he was now obliged to make a correction and say that she had taken poison. The poet, however, had been shot in a duel.

I now return to the brother's story, but from this point I must proceed for a little upon thematic lines. The boy's age at the time at which his sister began her seductions turned out to be three and a quarter years. It happened, as has been mentioned, in the spring of the same year in whose summer the English governess arrived, and in whose autumn his parents, on their return, found him so fundamentally altered. It is very natural, then, to connect this transformation with the awakening of his sexual activity that had meanwhile taken place.

How did the boy react to the allurements of his elder sister? By a refusal, is the answer, but by a refusal which applied to the person and not to the thing. His sister was not agreeable to him as a sexual object, probably because his relation to her had already been determined in a hostile direction owing to their rivalry for their parents' love. He held aloof from her, and, moreover, her solicitations soon ceased. But he tried to win, instead of her, another person of whom he was fonder; and the information which his sister herself had given him, and in which she had claimed his Nanya as a model, turned his choice in that direction. He therefore began to play with his penis in his Nanya's presence, and this, like so many other instances in which children do not conceal their masturbation, must be regarded as an attempt at seduction. His Nanya disillusioned him; she made a serious face, and explained that that wasn't good; children who did that, she added, got a 'wound' in the place.

The effect of this intelligence, which amounted to a threat, is to be traced in various directions. His dependence upon his Nanya was diminished in consequence. He might well have been angry with her; and later on, when his fits of rage set in, it became clear that he really was embittered against her. But it was characteristic of him that every position of the libido which he found himself obliged to abandon was at first obstinately defended by him against the new development. When the governess came upon the scene and abused his Nanya, drove her out of the room, and tried to destroy her authority, he, on the contrary, exaggerated his love for the victim of these attacks and assumed a brusque and defiant attitude towards the aggressive governess. Nevertheless, in secret he began to look about for another sexual object. His seduction had given him the passive sexual aim of being touched on the genitals; we shall presently hear in connection with whom it was that he tried to achieve this aim, and what paths led him to this choice.

It agrees entirely with our anticipations when we learn that, after his first genital excitations, his sexual researches began, and that he soon came upon the problem of castration. At this time he succeeded in observing two girls - his sister and a friend of hers - while they were micturating. His acumen might well have enabled him to gather the true facts from this spectacle, but he behaved as we know other male children behave in these circumstances. He rejected the idea that he saw before him a confirmation of the wound with which his Nanya had threatened him, and he explained to himself that this was the girls' 'front bottom'. The theme of castration was not settled by this decision; he found new allusions to it in everything that he heard. Once when the children were given some coloured sugar-sticks, the governess, who was inclined to disordered fancies, pronounced that they were pieces of chopped-up snakes. He remembered afterwards that his father had once met a snake while he was walking along a footpath, and had beaten it to pieces with his stick. He heard the story (out of *Reynard the Fox*) read aloud, of how the wolf wanted to go fishing in the winter, and used his tail as a bait, and how in that way his tail was broken off in the ice. He learned the different names by which horses are distinguished, according to whether their sexual organs are intact or not. Thus he was occupied with thoughts about castration, but as yet he had no belief in it and no dread of it. Other sexual problems arose for him out of the fairy tales with which he became familiar at this time. In 'Little Red Riding-Hood' and 'The Seven Little Goats' the children were taken out of the wolf's body. Was the wolf a female creature, then, or could men have children in their bodies as well? At this time the question was not yet settled. Moreover, at the time of these enquiries he had as yet no fear of wolves.

One of the patient's pieces of information will make it easier for us to understand the alteration in his character which appeared during his parents' absence as a somewhat indirect consequence of his seduction. He said that he gave up masturbating very soon after his Nanya's refusal and threat. *His sexual life, therefore, which was beginning to come under the sway of the genital zone, gave way before an external obstacle, and was thrown back by its influence into an earlier phase of pregenital organization.* As a result of the suppression of his masturbation, the boy's sexual life took on a sadistic-anal character. He became irritable and a tormentor, and gratified himself in this way at the expense of animals and humans. His principal object was his beloved Nanya, and he knew how to torment her till she burst into tears. In this way he revenged himself on her for the refusal he had met with, and at the same time gratified his sexual lust in the form which corresponded to his present regressive phase. He began to be cruel to small animals, to catch flies and pull off their wings, to crush beetles underfoot; in his imagination he liked beating large animals (horses) as well. All of these, then, were active and sadistic proceedings; we shall discuss his anal impulses at this period in a later connection.

It is a most important fact that some contemporary phantasies of quite another kind came up as well in the patient's memory. The content of these was of boys being chastised and beaten, and especially being beaten on the penis. And from other phantasies, which represented the heir to the throne being shut up in a narrow room and beaten, it was easy to guess for whom it was that the anonymous figures served as whipping-boys. The heir to the throne was evidently he himself; his sadism had therefore turned round in phantasy against himself, and had been converted into masochism. The detail of the sexual organ itself receiving the beating justified the conclusion that a sense of guilt, which related to his masturbation, was already concerned in this transformation.

No doubt was left in the analysis that these passive trends had made their appearance at the same time as the active-sadistic ones, or very soon after them.¹ This is in accordance with the unusually clear, intense, and constant *ambivalence* of the patient, which was shown here for the first time in the even development of both members of the pairs of contrary component instincts. Such behaviour was also characteristic of his later life, and so was this further trait: no position of the libido which had once been established was ever completely replaced by a later one. It was rather left in existence side by side with all the others, and this allowed him to maintain an incessant vacillation which proved to be incompatible with the acquisition of a stable character.

¹ By passive trends I mean trends that have a passive sexual aim; but in saying this I have in mind a transformation not of the instinct but only of its aim.

The boy's masochistic trends lead on to another point, which I have so far avoided mentioning, because it can only be confirmed by means of the analysis of the subsequent phase of his development. I have already mentioned that after his refusal by his Nanya his libidinal expectation detached itself from her and began to contemplate another person as a sexual object. This person was his father, at that time away from home. He was no doubt led to this choice by a number of convergent factors, including such fortuitous ones as the recollection of the snake being cut to pieces; but above all he was in this way able to renew his first and most primitive object-choice, which, in conformity with a small child's narcissism, had taken place along the path of identification. We have heard already that his father had been his admired model, and that when he was asked what he wanted to be he used to reply: a gentleman like his father. This object of identification of his active current became the sexual object of a passive current in his present anal-sadistic phase. It looks as though his seduction by his sister had forced him into a passive role, and had given him a passive sexual aim. Under the persisting influence of this experience he pursued a path from his sister *via* his Nanya to his father - from a passive attitude towards women to the same attitude towards men - and had, nevertheless, by this means found a link with his earlier and spontaneous phase of development. His father was now his object once more; in conformity with his higher stage of development, identification was replaced by object-choice; while the transformation of his active attitude into a passive one was the consequence and the record of the seduction which had occurred meanwhile. It would naturally not have been so easy to achieve an active attitude in the sadistic phase towards his all-powerful father. When his father came home in the late summer or autumn the patient's fits of rage and scenes of fury were put to a new use. They had served for active sadistic ends in relation to his Nanya; in relation to his father their purpose was masochistic. By bringing his naughtiness forward he was trying to force punishments and beatings out of his father, and in that way to obtain from him the masochistic sexual satisfaction that he desired. His screaming fits were therefore simply attempts at seduction. In accordance, moreover, with the motives which underlie masochism, this beating would also have satisfied his sense of guilt. He had preserved a memory of how, during one of these scenes of naughtiness, he had redoubled his screams as soon as his father came towards him. His father did not beat him, however, but tried to pacify him by playing ball in front of him with the pillows of his cot.

I do not know how often parents and educators, faced with inexplicable naughtiness on the part of a child, might not have occasion to bear this typical state of affairs in mind. A child who behaves in this unmanageable way is making a confession and trying to provoke punishment. He hopes for a beating as a simultaneous means of setting his sense of guilt at rest and of satisfying his masochistic sexual trend.

We owe the further explanation of the case to a recollection which emerged with great distinctness. This was to the effect that the signs of an alteration in the patient's character were not accompanied by any symptoms of anxiety until after the occurrence of a particular event. Previously, it seems, there was no anxiety, while directly after the event the anxiety expressed itself in the most tormenting shape. The date of this transformation can be stated with certainty; it was immediately before his fourth birthday. Taking this as a fixed point, we are able to divide the period of his childhood with which we are concerned into two phases: a first phase of naughtiness and perversity from his seduction at the age of three and a quarter up to his fourth birthday, and a longer subsequent phase in which the signs of neurosis predominated. But the event which makes this division possible was not an external trauma, but a dream, from which he awoke in a state of anxiety.

IV

THE DREAM AND THE PRIMAL SCENE

I have already published this dream elsewhere,¹ on account of the quantity of material in it which is derived from fairy tales; and I will begin by repeating what I wrote on that occasion:

"I dreamt that it was night and that I was lying in my bed. (My bed stood with its foot towards the window; in front of the window there was a row of old walnut trees. I know it was winter when I had the dream, and night-time.) Suddenly the window opened of its own accord, and I was terrified to see that some white wolves were sitting on the big walnut tree in front of the window. There were six or seven of them. The wolves were quite white, and looked more like foxes or sheep-dogs, for they had big tails like foxes and they had their ears pricked like dogs when they pay attention to something. In great terror, evidently of being eaten up by the wolves, I screamed and woke up. My nurse hurried to my bed, to see what had happened to me. It took quite a long while before I was convinced that it had only been a dream; I had had such a clear and life-like picture of the window opening and the wolves sitting on the tree. At last I grew quieter, felt as though I had escaped from some danger, and went to sleep again.

"The only piece of action in the dream was the opening of the window; for the wolves sat quite still and without making any movement on the branches of the tree, to the right and left of the trunk, and looked at me. It seemed as though they had riveted their whole attention upon me. - I think this was my first anxiety-dream. I was three, four, or at most five years old at the time. From then until my eleventh or twelfth year I was always afraid of seeing something terrible in my dreams."

He added a drawing of the tree with the wolves, which confirmed his description (Fig. 1). The analysis of the dream brought the following material to light.

He had always connected this dream with the recollection that during these years of his childhood he was most tremendously afraid of the picture of a wolf in a book of fairy tales. His elder sister, who was very much his superior, used to tease him by holding up this particular picture in front of him on some excuse or other, so that he was terrified and began to scream. In this picture the wolf was standing upright, striding out with one foot, with its claws stretched out and its ears pricked. He thought this picture must have been an illustration to the story of "Little Red Riding-Hood".

¹ 'The Occurrence in Dreams of Material from Fairy Tales' (1913*d*).

Fig. 1

‘Why were the wolves white? This made him think of the sheep, large flocks of which were kept in the neighbourhood of the estate. His father occasionally took him with him to visit these flocks, and every time this happened he felt very proud and blissful. Later on - according to enquiries that were made it may easily have been shortly before the time of the dream - an epidemic broke out among the sheep. His father sent for a follower of Pasteur’s, who inoculated the animals, but after the inoculation even more of them died than before.

'How did the wolves come to be on the tree? This reminded him of a story that he had heard his grandfather tell. He could not remember whether it was before or after the dream, but its subject is a decisive argument in favour of the former view. The story ran as follows. A tailor was sitting at work in his room, when the window opened and a wolf leapt in. The tailor hit after him with his yard - no (he corrected himself), caught him by his tail and pulled it off, so that the wolf ran away in terror. Some time later the tailor went into the forest, and suddenly saw a pack of wolves coming towards him; so he climbed up a tree to escape from them. At first the wolves were in perplexity; but the maimed one, which was among them and wanted to revenge himself on the tailor, proposed that they should climb one upon another till the last one could reach him. He himself - he was a vigorous old fellow - would be the base of the pyramid. The wolves did as he suggested, but the tailor had recognized the visitor whom he had punished, and suddenly called out as he had before: "Catch the grey one by his tail!" The tailless wolf, terrified by the recollection, ran away, and all the others tumbled down.

'In this story the tree appears, upon which the wolves were sitting in the dream. But it also contains an unmistakable allusion to the castration complex. The *old* wolf was docked of his tail by the tailor. The fox-tails of the wolves in the dream were probably compensations for this taillessness.

'Why were there six or seven wolves? There seemed to be no answer to this question, until I raised a doubt whether the picture that had frightened him could be connected with the story of "Little Red Riding-Hood". This fairy tale only offers an opportunity for two illustrations - Little Red Riding-Hood's meeting with the wolf in the wood, and the scene in which the wolf lies in bed in the grandmother's night-cap. There must therefore be some other fairy tale behind his recollection of the picture. He soon discovered that it could only be the story of "The Wolf and the Seven Little Goats". Here the number seven occurs, and also the number six, for the wolf only ate up six of the little goats, while the seventh hid itself in the clock case. The white, too, comes into this story, for the wolf had his paw made white at the baker's after the little goats had recognized him on his first visit by his grey paw. Moreover, the two fairy tales have much in common. In both there is the eating up, the cutting open of the belly, the taking out of the people who have been eaten and their replacement by heavy stones, and finally in both of them the wicked wolf perishes. Besides all this, in the story of the little goats the tree appears. The wolf lay down under a tree after his meal and snored.

'I shall have, for a special reason, to deal with this dream again elsewhere, and interpret it and consider its significance in greater detail. For it is the earliest anxiety-dream that the dreamer remembered from his childhood, and its content, taken in connection with other dreams that followed it soon afterwards and with certain events in his earliest years, is of quite peculiar interest. We must confine ourselves here to the relation of the dream to the two fairy tales which have so much in common with each other, "Little Red Riding-Hood" and "The Wolf and the Seven Little Goats". The effect produced by these stories was shown in the little dreamer by a regular animal phobia. This phobia was only distinguished from other similar cases by the fact that the anxiety-animal was not an object easily accessible to observation (such as a horse or a dog), but was known to him only from stories and picture-books.

'I shall discuss on another occasion the explanation of these animal phobias and the significance attaching to them. I will only remark in anticipation that this explanation is in complete harmony with the principal characteristic shown by the neurosis from which the present dreamer suffered later in his life. His fear of his father was the strongest motive for his falling ill, and his ambivalent attitude towards every father-surrogate was the dominating feature of his life as well as of his behaviour during the treatment.

'If in my patient's case the wolf was merely a first father surrogate, the question arises whether the hidden content in the fairy tales of the wolf that ate up the little goats and of "Little Red Riding-Hood" may not simply be infantile fear of the father.¹ Moreover, my patient's father had the characteristic, shown by so many people in relation to their children, of indulging in "affectionate abuse"; and it is possible that during the patient's earlier years his father (though he grew severe later on) may more than once, as he caressed the little boy or played with him, have threatened in fun to "gobble him up". One of my patients told me that her two children could never get to be fond of their grandfather, because in the course of his affectionate romping with them he used to frighten them by saying he would cut open their tummies.'

¹ 'Compare the similarity between these two fairy tales and the myth of Kronos, which has been pointed out by Rank (1912).'

Leaving on one side everything in this quotation that anticipates the dream's remoter implications, let us return to its immediate interpretation. I may remark that this interpretation was a task that dragged on over several years. The patient related the dream at a very early stage of the analysis and very soon came to share my conviction that the causes of his infantile neurosis lay concealed behind it. In the course of the treatment we often came back to the dream, but it was only during the last months of the analysis that it became possible to understand it completely, and only then thanks to spontaneous work on the patient's part. He had always emphasized the fact that two factors in the dream had made the greatest impression on him: first, the perfect stillness and immobility of the wolves, and secondly, the strained attention with which they all looked at him. The lasting sense of reality, too, which the dream left behind it, seemed to him to deserve notice.

Let us take this last remark as a starting-point. We know from our experience in interpreting dreams that this sense of reality carries a particular significance along with it. It assures us that some part of the latent material of the dream is claiming in the dreamer's memory to possess the quality of reality, that is, that the dream relates to an occurrence that really took place and was not merely imagined. It can naturally only be a question of the reality of something unknown; for instance, the conviction that his grandfather really told him the story of the tailor and the wolf, or that the stories of 'Little Red Riding-Hood' and of 'The Seven Little Goats' were really read aloud to him, would not be of a nature to be replaced by this sense of reality that outlasted the dream. The dream seemed to point to an occurrence the reality of which was very strongly emphasized as being in marked contrast to the unreality of the fairy tales.

If it was to be assumed that behind the content of the dream there lay some such unknown scene - one, that is, which had already been forgotten at the time of the dream - then it must have taken place very early. The dreamer, it will be recalled, said: 'I was three, four, or at most five years old at the time I had the dream.' And we can add: 'And I was reminded by the dream of something that must have belonged to an even earlier period.'

The parts of the manifest content of the dream which were emphasized by the dreamer, the factors of attentive looking and of motionlessness, must lead to the content of this scene. We must naturally expect to find that this material reproduces the unknown material of the scene in some distorted form, perhaps even distorted into its opposite.

There were several conclusions, too, to be drawn from the raw material which had been produced by the patient's first analysis of the dream, and these had to be fitted into the collocation of which we were in search. Behind the mention of the sheep-breeding, evidence was to be expected of his sexual researches, his interest in which he was able to gratify during his visits with his father; but there must also have been allusions to a fear of death, since the greater part of the sheep had died of the epidemic. The most obtrusive thing in the dream, the wolves on the tree, led straight to his grandfather's story; and what was fascinating about this story and capable of provoking the dream can scarcely have been anything but its connection with the theme of castration.

We also concluded from the first incomplete analysis of the dream that the wolf may have been a father-surrogate; so that, in that case, this first anxiety-dream would have brought to light the fear of his father which from that time forward was to dominate his life. This conclusion, indeed, was in itself not yet binding. But if we put together as the result of the provisional analysis what can be derived from the material produced by the dreamer, we then find before us for reconstruction some such fragments as these:

A real occurrence - dating from a very early period - looking - immobility - sexual problems - castration - his father - something terrible.

One day the patient began to continue with the interpretation of the dream. He thought that the part of the dream which said that 'suddenly the window opened of its own accord' was not completely explained by its connection with the window at which the tailor was sitting and through which the wolf came into the room. 'It must mean: "My eyes suddenly opened." I was asleep, therefore, and suddenly woke up, and as I woke I saw something: the tree with the wolves.' No objection could be made to this; but the point could be developed further. He had woken up and had seen something. The attentive looking, which in the dream was ascribed to the wolves, should rather be shifted on to him. At a decisive point, therefore, a transposition has taken place; and moreover this is indicated by another transposition in the manifest content of the dream. For the fact that the wolves were sitting on the tree was also a transposition, since in his grandfather's story they were underneath, and were unable to climb on to the tree.

What, then, if the other factor emphasized by the dreamer were also distorted by means of a transposition or reversal? In that case instead of immobility (the wolves sat there motionless; they looked at him, but did not move) the meaning would have to be: the most violent motion. That is to say, he suddenly woke up, and saw in front of him a scene of violent movement at which he looked with strained attention. In the one case the distortion would consist in an interchange of subject and object, of activity and passivity: being looked at instead of looking. In the other case it would consist in a transformation into the opposite; rest instead of motion.

On another occasion an association which suddenly occurred to him carried us another step forward in our understanding of the dream: 'The tree was a Christmas-tree.' He now knew that he had dreamt the dream shortly before Christmas and in expectation of it. Since Christmas Day was also his birthday, it now became possible to establish with certainty the date of the dream and of the change in him which proceeded from it. It was immediately before his fourth birthday. He had gone to sleep, then, in tense expectation of the day which ought to bring him a double quantity of presents. We know that in such circumstances a child may easily anticipate the fulfilment of his wishes. So it was already Christmas in his dream; the content of the dream showed him his Christmas box, the presents which were to be his were hanging on the tree. But instead of presents they had turned into - wolves, and the dream ended by his being overcome by fear of being eaten by the wolf (probably his father), and by his flying for refuge to his nurse. Our knowledge of his sexual development before the dream makes it possible for us to fill in the gaps in the dream and to explain the transformation of his satisfaction into anxiety. Of the wishes concerned in the formation of the dream the most powerful must have been the wish for the sexual satisfaction which he was at that time longing to obtain from his father. The strength of this wish made it possible to revive a long-forgotten trace in his memory of a scene which was able to show him what sexual satisfaction from his father was like; and the result was terror, horror of the fulfilment of the wish, the repression of the impulse which had manifested itself by means of the wish, and consequently a flight from his father to his less dangerous nurse.

The importance of this date of Christmas Day had been preserved in his supposed recollection of having had his first fit of rage because he was dissatisfied with his Christmas presents. The recollection combined elements of truth and of falsehood. It could not be entirely right, since according to the repeated declarations of his parents his naughtiness had already begun on their return in the autumn and it was not a fact that they had not come on till Christmas. But he had preserved the essential connection between his unsatisfied love, his rage, and Christmas.

But what picture can the nightly workings of his sexual desire have conjured up that could frighten him away so violently from the fulfilment for which he longed? The material of the analysis shows that there is one condition which this picture must satisfy. It must have been calculated to create a conviction of the reality of the existence of castration. Fear of castration could then become the motive power for the transformation of the affect.

I have now reached the point at which I must abandon the support I have hitherto had from the course of the analysis. I am afraid it will also be the point at which the reader's belief will abandon me.

What sprang into activity that night out of the chaos of the dreamer's unconscious memory-traces was the picture of copulation between his parents, copulation in circumstances which were not entirely usual and were especially favourable for observation. It gradually became possible to find satisfactory answers to all the questions that arose in connection with this scene; for in the course of the treatment the first dream returned in innumerable variations and new editions, in connection with which the analysis produced the information that was required. Thus in the first place the child's age at the date of the observation was established as being about one and a half years.¹ He was suffering at the time from malaria, an attack of which used to come on every day at a particular hour.² From his tenth year onwards he was from time to time subject to moods of depression, which used to come on in the afternoon and reached their height at about five o'clock. This symptom still existed at the time of the analytic treatment. The recurring fits of depression took the place of the earlier attacks of fever or languor; five o'clock was either the time of the highest fever or of the observation of the intercourse, unless the two times coincided.³ Probably for the very reason of this illness, he was in his parents' bedroom. The illness, the occurrence of which is also corroborated by direct tradition, makes it reasonable to refer the event to the summer, and, since the child was born on Christmas Day, to assume that his age was $n + 1\frac{1}{2}$ years. He had been sleeping in his cot, then, in his parents' bedroom, and woke up, perhaps because of his rising fever, in the afternoon, possibly at five o'clock, the hour which was later marked out by depression. It harmonizes with our assumption that it was a hot summer's day, if we suppose that his parents had retired, half undressed,⁴ for an afternoon *siesta*. When he woke up, he witnessed a coitus *a tergo* [from behind], three times repeated;⁵ he was able to see his mother's genitals as well as his father's organ; and he understood the process as well as its significance.⁶ Lastly he interrupted his parents' intercourse in a manner which will be discussed later.

¹ The age of six months came under consideration as a far less probable, and indeed scarcely tenable, alternative.

² Compare the subsequent metamorphoses of this factor during the obsessional neurosis. In the patient's dreams during the treatment it was replaced by a violent wind. [Added 1924:] 'Ayia' equals 'air'.

³ We may remark in this connection that the patient drew only *five* wolves in his illustration to the dream, although the text mentioned six or seven.

⁴ In white underclothes: the *white* wolves.

⁵ Why three times? He suddenly one day produced the statement that I had discovered this detail by interpretation. This was not the case. It was a spontaneous association, exempt from further criticism; in his usual way he passed it off on to me, and by this projection tried to make it seem more trustworthy.

⁶ I mean that he understood it at the time of the dream where he was four years old, not at the time of the observation. He received the impressions when he was one and a half; his understanding of them was deferred, but became possible at the time of the dream owing to his development, his sexual excitations, and his sexual researches.

There is at bottom nothing extraordinary, nothing to give the impression of being the product of an extravagant imagination, in the fact that a young couple who had only been married a few years should have ended a *siesta* on a hot summer's afternoon with a love-scene, and should have disregarded the presence of their little boy of one and a half, asleep in his cot. On the contrary, such an event would, I think, be something entirely commonplace and *banal*; and even the position in which we have inferred that the coitus took place cannot in the least alter this judgement - especially as the evidence does not require that the intercourse should have been performed from behind each time. A single time would have been enough to give the spectator an opportunity for making observations which would have been rendered difficult or impossible by any other attitude of the lovers. The content of the scene cannot therefore in itself be an argument against its credibility. Doubts as to its probability will turn upon three other points: whether a child at the tender age of one and a half could be in a position to take in the perceptions of such a complicated process and to preserve them so accurately in his unconscious; secondly, whether it is possible at the age of four for a deferred revision of the impressions so received to penetrate the understanding; and finally, whether any procedure could succeed in bringing into consciousness coherently and convincingly the details of a scene of this kind which had been experienced and understood in such circumstances.¹

¹ The first of these difficulties cannot be reduced by assuming that the child at the time of his observation was after all probably a year older, that is to say *two* and a half, an age at which he may perhaps have been perfectly capable of talking. All the minor details of my patient's case almost excluded the possibility of shifting the date in this way. Moreover, the fact should be taken into account that these scenes of observing parental intercourse are by no means rarely brought to light in analysis. The condition of their occurrence, however, is precisely that it should be in the earliest period of childhood. The older the child is, the more carefully, with parents above a certain social level, will the child be deprived of the opportunity for this kind of observation.

Later on I shall carefully examine these and other doubts; but I can assure the reader that I am no less critically inclined than he towards an acceptance of this observation of the child's, and I will only ask him to join me in adopting a *provisional* belief in the reality of the scene. We will first proceed with the study of the relations between this 'primal scene' and the patient's dream, his symptoms, and the history of his life; and we will trace separately the effects that followed from the essential content of the scene and from one of its visual impressions.

By the latter I mean the postures which he saw his parents adopt - the man upright, and the woman bent down like an animal. We have already heard that during his anxiety period his sister used to terrify him with a picture from the fairy-book, in which the wolf was shown standing upright, with one foot forward, with its claws stretched out and its ears pricked. He devoted himself with tireless perseverance during the treatment to the task of hunting in the second-hand book shops till he had found the illustrated fairy-book of his childhood, and had recognized his bogey in an illustration to the story of 'The Wolf and the Seven Little Goats'. He thought that the posture of the wolf in this picture might have reminded him of that of his father during the constructed primal scene. At all events the picture became the point of departure for further manifestations of anxiety. Once when he was in his seventh or eighth year he was informed that next day a new tutor was coming for him. That night he dreamt of this tutor in the shape of a lion that came towards his bed roaring loudly and in the posture of the wolf in the picture; and once again he awoke in a state of anxiety. The wolf phobia had been overcome by that time, so he was free to choose himself a new anxiety-animal, and in this late dream he was recognizing the tutor as a father-surrogate. In the later years of his childhood each of his tutors and masters played the part of his father, and was endowed with his father's influence both for good and for evil.

While he was at his secondary school the Fates provided him with a remarkable opportunity of reviving his wolf phobia, and of using the relation which lay behind it as an occasion for severe inhibitions. The master who taught his form Latin was called Wolf. From the very first he felt cowed by him, and he was once taken severely to task by him for having made a stupid mistake in a piece of Latin translation. From that time on he could not get free from a paralysing fear of this master, and it was soon extended to other masters besides. But the occasion on which he made his blunder in the translation was also to the purpose. He had to translate the Latin word '*filius*', and he did it with the French word '*fills*' instead of with the corresponding word from his own language. The wolf, in fact, was still his father.¹

The first 'transitory symptom'² which the patient produced during the treatment went back once more to the wolf phobia and to the fairy tale of 'The Seven Little Goats'. In the room in which the first sessions were held there was a large grandfather clock opposite the patient, who lay on a sofa facing away from me. I was struck by the fact that from time to time he turned his face towards me, looked at me in a very friendly way as though to propitiate me, and then turned his look away from me to the clock. I thought at the time that he was in this way showing his eagerness for the end of the hour. A long time afterwards the patient reminded me of this piece of dumb show, and gave me an explanation of it; for he recalled that the youngest of the seven little goats hid himself in the case of the grandfather clock while his six brothers were eaten up by the wolf. So what he had meant was: 'Be kind to me! Must I be frightened of you? Are you going to eat me up? Shall I hide myself from you in the clock-case like the youngest little goat?'

¹ After this reprimand from the schoolmaster-wolf he learnt that it was the general opinion of his companions that, to be pacified, the master expected money from him. We shall return to this point later. - I can see that it would greatly facilitate a rationalistic view of such a history of a child's development as this if it could be supposed that his whole fear of the wolf had really originated from the Latin master of that name, that it had been projected back into his childhood, and, supported by the illustration to the fairy tale, had caused the phantasy of the primal scene. But this is untenable; the chronological priority of the wolf phobia and its reference to the period of his childhood spent upon the first estate is far too securely attested. And his dream at the age of four?

² Ferenczi (1912).

The wolf that he was afraid of was undoubtedly his father; but his fear of the wolf was conditional upon the creature being in an upright posture. His recollection asserted most definitely that he had not been terrified by pictures of wolves going on all fours or, as in the story of 'Little Red Riding-Hood', lying in bed. The posture which, according to our construction of the primal scene, he had seen the woman assume, was of no less significance; though in this case the significance was limited to the sexual sphere. The most striking phenomenon of his erotic life after maturity was his liability to compulsive attacks of falling physically in love which came on and disappeared again in the most puzzling succession. These attacks released a tremendous energy in him even at times when he was otherwise inhibited, and they were quite beyond his control. I must, for a specially important reason, postpone a full consideration of this compulsive love; but I may mention here that it was subject to a definite condition, which was concealed from his consciousness and was discovered only during the treatment. It was necessary that the woman should have assumed the posture which we have ascribed to his mother in the primal scene. From his puberty he had felt large and conspicuous buttocks as the most powerful attraction in a woman; to copulate except from behind gave him scarcely any enjoyment. At this point a criticism may justly be raised: it may be objected that a sexual preference of this kind for the hind parts of the body is a general characteristic of people who are inclined to an obsessional neurosis, and that its presence does not justify us in referring it back to a special impression in childhood. It is part of the fabric of the anal-erotic disposition and is one of the archaic traits which distinguish that constitution. Indeed, copulation from behind - *more ferarum* [in the fashion of animals] - may, after all, be regarded as phylogenetically the older form. We shall return to this point too in a later discussion, when we have brought forward the supplementary material which showed the basis of the unconscious condition upon which his falling in love depended.

Let us now proceed with our discussion of the relations between his dream and the primal scene. We should so far have expected the dream to present the child (who was rejoicing at Christmas in the prospect of the fulfilment of his wishes) with this picture of sexual satisfaction afforded through his father's agency, just as he had seen it in the primal scene, as a model of the satisfaction that he himself was longing to obtain from his father. Instead of this picture, however, there appeared the material of the story which he had been told by his grandfather shortly before: the tree, the wolves, and the taillessness (in the over-compensated form of the bushy tails of the putative wolves). At this point some connection is missing, some associative bridge to lead from the content of the primal scene to that of the wolf story. This connection is provided once again by the postures and only by them. In his grandfather's story the tailless wolf asked the others *to climb upon him*. It was this detail that called up the recollection of the picture of the primal scene; and it was in this way that it became possible for the material of the primal scene to be represented by that of the wolf story, and at the same time for the *two* parents to be replaced, as was desirable, by *several* wolves. The content of the dream met with a further transformation, and the material of the wolf story was made to fit in with the content of the fairy tale of 'The Seven Little Goats', by borrowing from it the number seven.¹

The steps in the transformation of the material, 'primal scene - wolf story - fairy tale of "The Seven Little Goats"', are a reflection of the progress of the dreamer's thoughts during the construction of the dream: 'longing for sexual satisfaction from his father - realization that castration is a necessary condition of it - fear of his father'. It is only at this point, I think, that we can regard the anxiety-dream of this four-year-old boy as being exhaustively explained.²

¹ It says 'six or seven' in the dream. Six is the number of the children that were eaten; the seventh escaped into the clock-case. It is always a strict law of dream-interpretation that an explanation must be found for every detail.

² Now that we have succeeded in making a synthesis of the dream, I will try to give a comprehensive account of the relations between the manifest content of the dream and the latent dream-thoughts.

It was night, I was lying in my bed. The latter part of this is the beginning of the reproduction of the primal scene. 'It was night' is a distortion of 'I had been asleep'. The remark, 'I know it was winter when I had the dream, and night-time', refers to the patient's recollection of the dream and is not part of its content. It is correct, for it was one of the nights before his birthday, that is, Christmas Day.

Suddenly the window opened of its own accord. That is to be translated: 'Suddenly I woke up of my own accord', a recollection of the primal scene. The influence of the wolf story, in which the wolf leapt in through the window, is making itself felt as a modifying factor, and transforms a direct expression into a plastic one. At the same time the introduction of the window serves the purpose of providing a contemporary reference for the subsequent content of the dream. On Christmas Eve the door opens suddenly and one sees before one the tree with the presents. Here therefore the influence of the actual expectation of Christmas (which comprises the wish for sexual satisfaction) is making itself felt.

The big walnut tree. The representative of the Christmas tree, and therefore belonging to the current situation. But also the tree out of the wolf story, on which the tailor took refuge from pursuit, and under which the wolves were on the watch. Moreover, as I have often been able to satisfy myself, a high tree is a symbol of observing, of scopophilia. A person sitting on a tree can see everything that is going on below him and cannot himself be seen. Compare Boccaccio's well-known story, and similar *facetiae*.

The wolves. Their number: *six or seven*. In the wolf story there was a pack, and no number was given. The fixing of the number shows the influence of the fairy tale of 'The Seven Little Goats', six of whom were eaten up. The fact that the number two in the primal scene is replaced by a larger number, which would be absurd in the primal scene, is welcomed by the resistance as a means of distortion. In the illustration to the dream the dreamer brings forward the number five, which is probably meant to correct the statement 'It was night'.

They were sitting on the tree. In the first place they replace the Christmas presents hanging on the tree. But they are also transposed on to the tree because that can mean that they are looking. In his grandfather's story they were posted underneath the tree. Their relation to the tree has therefore been reversed in the dream; and from this it may be concluded that there are further reversals of the latent material to be found in the content of the dream.

They were looking at him with strained attention. This feature comes entirely from the primal scene, and has got into the dream at the price of being turned completely round.

They were quite white. This feature is unessential in itself, but is strongly emphasized in the dreamer's narrative. It owes its intensity to a copious fusion of elements from all the strata of the material, and it combines unimportant details from the other sources of the dream with a fragment of the primal scene which is more significant. This last part of its determination goes back to the white of his parents' bedclothes and underclothes, and to this is added the white of the flocks of sheep, and of the sheep-dogs, as an allusion to his sexual researches among animals, and the white in the fairy tale of 'The Seven Little Goats', in which the mother is recognized by the white of her hand. Later on we shall see that the white clothes are also an allusion to death.

They sat there motionless. This contradicts the most striking feature of the observed scene, namely, its agitated movement, which, in virtue of the postures to which it led, constitutes the connection between the primal scene and the wolf story.

They had tails like foxes. This must be the contradiction of a conclusion which was derived from the action of the primal scene on the wolf story, and which must be recognized as the most important result of the dreamer's sexual

From The History Of An Infantile Neurosis

researches: 'So there really is such a thing as castration.' The terror with which this conclusion was received finally broke out in the dream and brought it to an end.

The fear of being eaten up by the wolves. It seemed to the dreamer as though the motive force of this fear was not derived from the content of the dream. He said he need not have been afraid, for the wolves looked more like foxes or dogs, and they did not rush at him as though to bite him, but were very still and not at all terrible. We observe that the dream-work tries for some time to make the distressing content harmless by transforming it into its opposite. ('They aren't moving, and, only look, they have the loveliest tails!') Until at last this expedient fails, and the fear breaks out. It expresses itself by the help of the fairy tale, in which the goat-children are eaten up by the wolf-father. This part of the fairy tale may perhaps have acted as a reminder of threats made by the child's father in fun when he was playing with him; so that the fear of being eaten up by the wolf may be a reminiscence as well as a substitute by displacement.

The wishes which act as motive forces in this dream are obvious. First there are the superficial wishes of the day, that Christmas with its presents may already be here (a dream of impatience) and accompanying these is the deeper wish, now permanently present, for sexual satisfaction from the dreamer's father. This is immediately replaced by the wish to see once more what was then so fascinating. The mental process then proceeds on its way. Starting from the fulfilment of this last wish with the conjuring up of the primal scene, it passes on to what has now become inevitable - the repudiation of that wish and its repression.

The diffuseness and elaboration of this commentary have been forced on me by the effort to present the reader with some sort of equivalent for the convincing power of an analysis carried through by oneself; perhaps they may also serve to discourage him from asking for the publication of analyses which have stretched over several years.

After what has already been said I need only deal shortly with the pathogenic effect of the primal scene and the alteration which its revival produced in his sexual development. We will only trace that one of its effects to which the dream gave expression. Later on we shall have to make it clear that it was not only a single sexual current that started from the primal scene but a whole set of them, that his sexual life was positively splintered up by it. We shall further bear in mind that the activation of this scene (I purposely avoid the word 'recollection') had the same effect as though it were a recent experience. The effects of the scene were deferred, but meanwhile it had lost none of its freshness in the interval between the ages of one and a half and four years. We shall perhaps find in what follows reason to suppose that it produced certain effects even at the time of its perception, that is, from the age of one and a half onwards.

When the patient entered more deeply into the situation of the primal scene, he brought to light the following pieces of self-observation. He assumed to begin with, he said, that the event of which he was a witness was an act of violence, but the expression of enjoyment which he saw on his mother's face did not fit in with this; he was obliged to recognize that the experience was one of gratification.¹ What was essentially new for him in his observation of his parents' intercourse was the conviction of the reality of castration - a possibility with which his thoughts had already been occupied previously. (The sight of the two girls micturating, his Nanya's threat, the governess' interpretation of the sugar-sticks, the recollection of his father having beaten a snake to pieces.) For now he saw with his own eyes the wound of which his Nanya had spoken, and understood that its presence was a necessary condition of intercourse with his father. He could no longer confuse it with the bottom, as he had in his observation of the little girls.²

¹ We might perhaps best do justice to this statement of the patient's by supposing that the object of his observation was in the first instance a coitus in the normal position, which cannot fail to produce the impression of being a sadistic act, and that only after this was the position altered, so that he had an opportunity for making other observations and judgements. This hypothesis, however, was not confirmed with certainty, and moreover does not seem to me indispensable. We must not forget the actual situation which lies behind the abbreviated description given in the text: the patient under analysis, at an age of over twenty-five years, was putting the impressions and impulses of his fourth year into words which he would never have found at that time. If we fail to notice this, it may easily seem comic and incredible that a child of four should be capable of such technical judgements and learned notions. This is simply another instance of *deferred action*. At the age of one and a half the child receives an impression to which he is unable to react adequately; he is only able to understand it and to be moved by it when the impression is revived in him at the age of four; and only twenty years later, during the analysis, is he able to grasp with his conscious mental processes what was then going on in him. The patient justifiably disregards the three periods of time, and puts his present ego into the situation which is so long past. And in this we follow him, since with correct self-observation and interpretation the effect must be the same as though the distance between the second and third periods of time could be neglected. Moreover, we have no other means of describing the events of the second period.

² We shall learn later on, when we come to trace out his anal erotism, how he further dealt with this portion of the problem.

The dream ended in a state of anxiety, from which he did not recover until he had his Nanya with him. He fled, therefore, from his father to her. His anxiety was a repudiation of the wish for sexual satisfaction from his father - the trend which had put the dream into his head. The form taken by the anxiety, the fear of 'being eaten by the wolf', was only the (as we shall hear, regressive) transposition of the wish to be copulated with by his father, that is, to be given sexual satisfaction in the same way as his mother. His last sexual aim, the passive attitude towards his father, succumbed to repression, and fear of his father appeared in its place in the shape of the wolf phobia.

And the driving force of this repression? The circumstances of the case show that it can only have been his narcissistic genital libido which, in the form of concern for his male organ, was fighting against a satisfaction whose attainment seemed to involve the renunciation of that organ. And it was from his threatened narcissism that he derived the masculinity with which he defended himself against his passive attitude towards his father.

We now observe that at this point in our narrative we must make an alteration in our terminology. During the dream he had reached a new phase in his sexual organization. Up to then the sexual opposites had been for him *active* and *passive*. Since his seduction his sexual aim had been a passive one, of being touched on the genitals; it was then transformed, by regression to the earlier stage of the sadistic-anal organization, into the masochistic aim of being beaten or punished. It was a matter of indifference to him whether he reached this aim with a man or with a woman. He had travelled, without considering the difference of sex, from his Nanya to his father; he had longed to have his penis touched by his Nanya, and had tried to provoke a beating from his father. Here his genitals were left out of account; though the connection with them which had been concealed by the regression was still expressed in his phantasy of being beaten *on the penis*. The activation of the primal scene in the dream now brought him back to the genital organization. He discovered the vagina and the biological significance of masculine and feminine. He understood now that active was the same as masculine, while passive was the same as feminine. His passive sexual aim should now have been transformed into a feminine one, and have expressed itself as 'being copulated with by his father' instead of 'being beaten by him on the genitals or on the bottom'. This feminine aim, however, underwent repression and was obliged to let itself be replaced by fear of the wolf.

We must here break off the discussion of his sexual development until new light is thrown from the later stages of his history upon these earlier ones. For the proper appreciation of the wolf phobia we will only add that both his father and mother became wolves. His mother took the part of the castrated wolf, which let the others climb upon it; his father took the part of the wolf that climbed. But his fear, as we have heard him assure us, related only to the standing wolf, that is, to his father. It must further strike us that the fear with which the dream ended had a model in his grandfather's story. For in this the castrated wolf, which had let the others climb upon it, was seized with fear as soon as it was reminded of the fact of its taillessness. It seems, therefore, as though he had identified himself with his castrated mother during the dream, and was now fighting against that fact. 'If you want to be sexually satisfied by Father', we may perhaps represent him as saying to himself, 'you must allow yourself to be castrated like Mother; but I won't have that.' In short, a clear protest on the part of his masculinity! Let us, however, plainly understand that the sexual development of the case that we are now examining has a great disadvantage from the point of view of research, for it was by no means undisturbed. It was first decisively influenced by the seduction, and was then diverted by the scene of observation of the coitus, which in its deferred action operated like a second seduction.

V

A FEW DISCUSSIONS

The whale and the polar bear, it has been said, cannot wage war on each other, for since each is confined to his own element they cannot meet. It is just as impossible for me to argue with workers in the field of psychology or of the neuroses who do not recognize the postulates of psycho-analysis and who look on its results as artefacts. But during the last few years there has grown up another kind of opposition as well, among people who, in their own opinion at all events, take their stand upon the ground of analysis, who do not dispute its technique or results, but who merely think themselves justified in drawing other conclusions from the same material and in submitting it to other interpretations.

As a rule, however, theoretical controversy is unfruitful. No sooner has one begun to depart from the material on which one ought to be relying, than one runs the risk of becoming intoxicated with one's own assertions and, in the end, of supporting opinions which any observation would have contradicted. For this reason it seems to me to be incomparably more useful to combat dissentient interpretations by testing them upon particular cases and problems.

I have remarked above (see [p. 3528](#)) that it will certainly be considered improbable, firstly, that 'a child at the tender age of one and a half could be in a position to take in the perceptions of such a complicated process and to preserve them so accurately in his unconscious; secondly, that it is possible at the age of four for a deferred revision of this material to penetrate the understanding; and finally, that any procedure could succeed in bringing into consciousness coherently and convincingly the details of a scene of this kind which had been experienced and understood in such circumstances'.

The last question is purely one of fact. Anyone who will take the trouble of pursuing an analysis into these depths by means of the prescribed technique will convince himself that it is decidedly possible. Anyone who neglects this, and breaks off the analysis in some higher stratum, has waived his right of forming a judgement on the matter. But the interpretation of what is arrived at in depth-analysis is not decided by this.

The two other doubts are based on a low estimate of the importance of early infantile impressions and an unwillingness to ascribe such enduring effects to them. The supporters of this view look for the causes of neuroses almost exclusively in the grave conflicts of later life; they assume that the importance of childhood is only held up before our eyes in analysis on account of the inclination of neurotics for expressing their present interests in reminiscences and symbols from the remote past. Such an estimate of the importance of the infantile factor would involve the disappearance of much that has formed part of the most intimate characteristics of analysis, though also, no doubt, of much that raises resistance to it and alienates the confidence of the outsider.

The view, then, that we are putting up for discussion is as follows. It maintains that scenes from early infancy, such as are brought up by an exhaustive analysis of neuroses (as, for instance, in the present case), are not reproductions of real occurrences, to which it is possible to ascribe an influence over the course of the patient's later life and over the formation of his symptoms. It considers them rather as products of the imagination, which find their instigation in mature life, which are intended to serve as some kind of symbolic representation of real wishes and interests, and which owe their origin to a regressive tendency, to a turning-away from the tasks of the present. If that is so, we can of course spare ourselves the necessity of attributing such a surprising amount to the mental life and intellectual capacity of children of the tenderest age.

Besides the desire which we all share for the rationalization and simplification of our difficult problem, there are all sorts of facts that speak in favour of this view. It is also possible to eliminate beforehand one objection to it which may arise, particularly in the mind of a practising analyst. It must be admitted that, if this view of these scenes from infancy were the right one, the carrying-out of analysis would not in the first instance be altered in any respect. If neurotics are endowed with the evil characteristic of diverting their interest from the present and of attaching it to these regressive substitutes, the products of their imagination, then there is absolutely nothing for it but to follow upon their tracks and bring these unconscious productions into consciousness; for, leaving on one side their lack of value from the point of view of reality, they are of the utmost value from our point of view, since they are for the moment the bearers and possessors of the interest which we want to set free so as to be able to direct it on to the tasks of the present. The analysis would have to run precisely the same course as one which had a *naïf* faith in the truth of the phantasies. The difference would only come at the end of the analysis, after the phantasies had been laid bare. We should then say to the patient: 'Very well, then; your neurosis proceeded *as though* you had received these impressions and spun them out in your childhood. You will see, of course, that that is out of the question. They were products of your imagination which were intended to divert you from the real tasks that lay before you. Let us now enquire what these tasks were, and what lines of communication ran between them and your phantasies.' After the infantile phantasies had been disposed of in this way, it would be possible to begin a second portion of the treatment, which would be concerned with the patient's real life.

Any shortening of this course, any alteration, that is, in psycho-analytic treatment, as it has hitherto been practised, would be technically inadmissible. Unless these phantasies are made conscious to the patient to their fullest extent, he cannot obtain command of the interest which is attached to them. If his attention is diverted from them as soon as their existence and their general outlines are divined, support is simply being given to the work of repression, thanks to which they have been put beyond the patient's reach in spite of all his pains. If he is given a premature sense of their unimportance, by being informed, for instance, that it will only be a question of phantasies, which, of course, have no real significance, his co-operation will never be secured for the task of bringing them into consciousness. A correct procedure, therefore, would make no alteration in the technique of analysis, whatever estimate might be formed of these scenes from infancy.

I have already mentioned that there are a number of facts which can be brought up in support of the view of these scenes being regressive phantasies. And above all there is this one: so far as my experience hitherto goes, these scenes from infancy are not reproduced during the treatment as recollections, they are the products of construction. Many people will certainly think that this single admission decides the whole dispute.

I am anxious not to be misunderstood. Every analyst knows - and he has met with the experience on countless occasions - that in the course of a successful treatment the patient brings up a large number of spontaneous recollections from his childhood, for the appearance of which (a first appearance, perhaps) the physician feels himself entirely blameless, since he has not made any attempt at a construction which could have put any material of the sort into the patient's head. It does not necessarily follow that these previously unconscious recollections are always true. They may be; but they are often distorted from the truth, and interspersed with imaginary elements, just like the so-called screen memories which are preserved spontaneously. All that I mean to say is this: scenes, like this one in my present patient's case, which date from such an early period and exhibit a similar content, and which further lay claim to such an extraordinary significance for the history of the case, are as a rule not reproduced as recollections, but have to be divined - constructed - gradually and laboriously from an aggregate of indications. Moreover, it would be sufficient for the purposes of the argument if my admission that scenes of this kind do not become conscious in the shape of recollections applied only to cases of obsessional neurosis, or even if I were to limit my assertion to the case which we are studying here.

I am not of opinion, however, that such scenes must necessarily be phantasies because they do not reappear in the shape of recollections. It seems to me absolutely equivalent to a recollection, if the memories are replaced (as in the present case) by dreams the analysis of which invariably leads back to the same scene and which reproduce every portion of its content in an inexhaustible variety of new shapes. Indeed, dreaming is another kind of remembering, though one that is subject to the conditions that rule at night and to the laws of dream-formation. It is this recurrence in dreams that I regard as the explanation of the fact that the patients themselves gradually acquire a profound conviction of the reality of these primal scenes, a conviction which is in no respect inferior to one based on recollection.¹

¹ A passage in the first edition of my *Interpretation of Dreams* (1900a) will show at what an early stage I was occupied with this problem. On p. 670 of that work there is an analysis of a remark occurring in a dream: '*That's not obtainable any longer.*' It is explained that the phrase originated from myself. 'A few days earlier I had explained to the patient that the earliest experiences of childhood were "*not obtainable any longer* as such" but were replaced in analysis by "transferences" and dreams.'

There is naturally no need for those who take the opposite view to abandon as hopeless their fight against such arguments. It is well known that dreams can be guided.¹ And the sense of conviction felt by the person analysed may be the result of suggestion, which is always having new parts assigned to it in the play of forces involved in analytic treatment. The old-fashioned psychotherapist, it might be maintained, used to suggest to his patient that he was cured, that he had overcome his inhibitions, and so on; while the psycho-analyst, on this view, suggests to him that when he was a child he had some experience or other, which he must now recollect in order to be cured. This would be the difference between the two.

Let it be clearly understood that this last attempt at an explanation on the part of those who take the view opposed to mine results in the scenes from infancy being disposed of far more fundamentally than was announced to begin with. What was argued at first was that they were not realities but phantasies. But what is argued now is evidently that they are phantasies not of the patient but of the analyst himself, who forces them upon the person under analysis on account of some complexes of his own. An analyst, indeed, who hears this reproach, will comfort himself by recalling how gradually the construction of this phantasy which he is supposed to have originated came about, and, when all is said and done, how independently of the physician's incentive many points in its development proceeded; how, after a certain phase of the treatment, everything seemed to converge upon it, and how later, in the synthesis, the most various and remarkable results radiated out from it; how not only the large problems but the smallest peculiarities in the history of the case were cleared up by this single assumption. And he will disclaim the possession of the amount of ingenuity necessary for the concoction of an occurrence which can fulfil all these demands. But even this plea will be without an effect on an adversary who has not experienced the analysis himself. On the one side there will be a charge of subtle self-deception, and on the other of obtuseness of judgement; it will be impossible to arrive at a decision.

¹ The *mechanism* of dreaming cannot be influenced; but dream *material* is to some extent subject to orders.

Let us turn to another factor which supports this opposing view of these constructed scenes from infancy. It is as follows: There can be no doubt of the real existence of all the processes which have been brought forward in order to explain these doubtful structures as phantasies, and their importance must be recognized. The diversion of interest from the tasks of real life,¹ the existence of phantasies in the capacity of substitutes for unperformed actions, the regressive tendency which is expressed in these productions - regressive in more than one sense, in so far as there is involved simultaneously a shrinking-back from life and a harking-back to the past - all these things hold good, and are regularly confirmed by analysis. One might think that they would also suffice to explain the supposed reminiscences from early infancy which are under discussion; and in accordance with the principle of economy in science such an explanation would have the advantage over one which is inadequate without the support of new and surprising assumptions.

I may here venture to point out that the antagonistic views which are to be found in the psycho-analytic literature of to-day are usually arrived at on the principle of *pars pro toto*. From a highly composite combination one part of the operative factors is singled out and proclaimed as the truth; and in its favour the other part, together with the whole combination, is then contradicted. If we look a little closer, to see which group of factors it is that has been given the preference, we shall find that it is the one that contains material already known from other sources or what can be most easily related to that material. Thus, Jung picks out actuality and regression, and Adler, egoistic motives. What is left over, however, and rejected as false, is precisely what is new in psycho-analysis and peculiar to it. This is the easiest method of repelling the revolutionary and inconvenient advances of psycho-analysis.

¹ I have good reasons for preferring to say 'the diversion of *libido* from current *conflicts*'.

It is worth while remarking that none of the factors which are adduced by the opposing view in order to explain these scenes from infancy had to wait for recognition until Jung brought them forward as novelties. The notion of a current conflict, of a turning away from reality, of a substitutive satisfaction obtained in phantasy, of a regression to material from the past - all of this (employed, moreover, in the same context, though perhaps with a slightly different terminology) had for years formed an integral part of my own theory. It was not the whole of it, however. It was only one part of the causes leading to the formation of neuroses - that part which, starting from reality, operates in a regressive direction. Side by side with this I left room for another influence which, starting from the impressions of childhood, operates in a forward direction, which points a path for the libido that is shrinking away from life, and which makes it possible to understand the otherwise inexplicable regression to childhood. Thus on my view the two factors co-operate in the formation of symptoms. But an earlier co-operation seems to me to be of equal importance. I am of opinion that *the influence of childhood makes itself felt already in the situation at the beginning of the formation of a neurosis, since it plays a decisive part in determining whether and at what point the individual shall fail to master the real problems of life.*

What is in dispute, therefore, is the significance of the infantile factor. The problem is to find a case which can establish that significance beyond any doubt. Such, however, is the case which is being dealt with so exhaustively in these pages and which is distinguished by the characteristic that the neurosis in later life was preceded by a neurosis in early childhood. It is for that very reason, indeed, that I have chosen it to report upon. Should any one feel inclined to reject it because the animal phobia strikes him as not sufficiently serious to be recognized as an independent neurosis, I may mention that the phobia was succeeded without any interval by an obsessional ceremonial, and by obsessional acts and thoughts, which will be discussed in the following sections of this paper.

The occurrence of a neurotic disorder in the fourth and fifth years of childhood proves, first and foremost, that infantile experiences are by themselves in a position to produce a neurosis, without there being any need for the addition of a flight from some task which has to be faced in real life. It may be objected that even a child is constantly being confronted with tasks which it would perhaps be glad to evade. That is so; but the life of a child under school age is easily observable, and we can examine it to see whether any 'tasks' are to be found in it capable of determining the causation of a neurosis. But we discover nothing but instinctual impulses which the child cannot satisfy and which it is not old enough to master, and the sources from which these impulses arise.

As was to be expected, the enormous shortening of the interval between the outbreak of the neurosis and the date of the childhood experiences which are under discussion reduces to the narrowest limits the regressive part of the causation, while it brings into full view the portion of it which operates in a forward direction, the influence of earlier impressions. The present case history will, I hope, give a clear picture of this position of things. But there are other reasons why neuroses of childhood give a decisive answer to the question of the nature of primal scenes - the earliest experiences of childhood that are brought to light in analysis.

Let us assume as an uncontradicted premise that a primal scene of this kind has been correctly deduced technically, that it is indispensable to a comprehensive solution of all the conundrums that are set us by the symptoms of the infantile disorder, that all the consequences radiate out from it, just as all the threads of the analysis have led up to it. Then, in view of its content, it is impossible that it can be anything else than the reproduction of a reality experienced by the child. For a child, like an adult, can produce phantasies only from material which has been acquired from some source or other; and with children, some of the means of acquiring it (by reading, for instance) are cut off, while the space of time at their disposal for acquiring it is short and can easily be searched with a view to the discovery of any such sources.

In the present case the content of the primal scene is a picture of sexual intercourse between the boy's parents in a posture especially favourable for certain observations. Now it would be no evidence whatever of the reality of such a scene if we were to find it in a patient whose symptoms (the effects of the scene, that is) had appeared at some time or other in the later part of his life. A person such as this might have acquired the impressions, the ideas, and the knowledge on a great number of different occasions in the course of the long interval; he might then have transformed them into an imaginary picture, have projected them back into his childhood, and have attached them to his parents. If, however, the effects of a scene of this sort appear in the child's fourth or fifth year, then he must have witnessed the scene at an age even earlier than that. But in that case we are still faced with all the disconcerting consequences which have arisen from the analysis of this infantile neurosis. The only way out would be to assume that the patient not only unconsciously imagined the primal scene, but also concocted the alteration in his character, his fear of the wolf, and his religious obsession; but such an expedient would be contradicted by his otherwise sober nature and by the direct tradition in his family. It must therefore be left at this (I can see no other possibility): either the analysis based on the neurosis in his childhood is all a piece of nonsense from start to finish, or everything took place just as I have described it above.

At an earlier stage in the discussion we were brought up against an ambiguity in regard to the patient's predilection for female nates and for sexual intercourse in the posture in which they are especially prominent. It seemed necessary to trace this predilection back to the intercourse which he had observed between his parents, while at the same time a preference of this kind is a general characteristic of archaic constitutions which are predisposed to an obsessional neurosis. But the contradiction is easily resolved if we regard it as a case of overdetermination. The person who was the subject of his observation of this posture during intercourse was, after all, his father in the flesh, and it may also have been from him that he had inherited this constitutional predilection. Neither his father's subsequent illness nor his family history contradicts this; as has been mentioned already, a brother of his father's died in a condition which must be regarded as the outcome of a severe obsessional disorder.

In this connection we may recall that, at the time of his seduction as a boy of three and a quarter, his sister had uttered a remarkable calumny against his good old nurse, to the effect that she stood all kinds of people on their heads and then took hold of them by their genitals. We cannot fail to be struck by the idea that perhaps the sister, at a similar tender age, also witnessed the same scene as was observed by her brother later on, and that it was this that had suggested to her her notion about 'standing people on their heads' during the sexual act. This hypothesis would also give us a hint of the reason for her own sexual precocity.

[Originally ¹ I had no intention of pursuing the discussion of the reality of 'primal scenes' any further in this place. Since, however, I have meanwhile had occasion in my *Introductory Lectures on Psycho-Analysis* to treat the subject on more general lines and with no controversial aim in view, it would be misleading if I omitted to apply the considerations which determined my other discussion of the matter to the case that is now before us. I therefore proceed as follows by way of supplement and rectification. - There remains the possibility of taking yet another view of the primal scene underlying the dream - a view, moreover, which obviates to a large extent the conclusion that has been arrived at above and relieves us of many of our difficulties. But the theory which seeks to reduce scenes from infancy to the level of regressive symbols will gain nothing even by this modification; and indeed that theory seems to me to be finally disposed of by this (as it would be by any other) analysis of an infantile neurosis.

This other view which I have in mind is that the state of affairs can be explained in the following manner. It is true that we cannot dispense with the assumption that the child observed a copulation, the sight of which gave him a conviction that castration might be more than an empty threat. Moreover, the significance which he subsequently came to attach to the postures of men and women, in connection with the development of anxiety on the one hand, and as a condition upon which his falling in love depended on the other hand, leaves us no choice but to conclude that it must have been a *coitus a tergo, more ferarum*. But there is another factor which is not so irreplaceable and which may be dropped. Perhaps what the child observed was not copulation between his parents but copulation between animals, which he then displaced on to his parents, as though he had inferred that his parents did things in the same way.

¹ [Freud's square brackets]

Colour is lent to this view above all by the fact that the wolves in the dream were actually sheep-dogs and, moreover, appear as such in the drawing. Shortly before the dream the boy was repeatedly taken to visit the flocks of sheep, and there he might see just such large white dogs and probably also observe them copulating. I should also like to bring into this connection the number three, which the dreamer introduced without adducing any further motive, and I would suggest that he had kept in his memory the fact that he had made three such observations with the sheep-dogs. What supervened during the expectant excitement of the night of his dream was the transference on to his parents of his recently acquired memory-picture, with *all* its details, and it was only thus that the powerful emotional effects which followed were made possible. He now arrived at a deferred understanding of the impressions which he may have received a few weeks or months earlier - a process such as all of us perhaps have been through in our own experiences. The transference from the copulating dogs on to his parents was accomplished not by means of his making an inference accompanied by words but by his searching out in his memory a real scene in which his parents had been together and which could be coalesced with the situation of the copulation. All the details of the scene which were established in the analysis of the dream may have been accurately reproduced. It was really on a summer's afternoon while the child was suffering from malaria, the parents were both present, dressed in white, when the child woke up from his sleep, but - the scene was innocent. The rest had been added by the inquisitive child's subsequent wish, based on his experiences with the dogs, to witness his parents too in their love-making; and the scene which was thus imagined now produced all the effects that we have catalogued, just as though it had been entirely real and not fused together out of two components, the one earlier and indifferent, the other later and profoundly impressive.

It is at once obvious how greatly the demands on our credulity are reduced. We need no longer suppose that the parents copulated in the presence of their child (a very young one, it is true) - which was a disagreeable idea for many of us. The period of time during which the effects were deferred is very greatly diminished; it now covers only a few months of the child's fourth year and does not stretch back at all into the first dark years of childhood. There remains scarcely anything strange in the child's conduct in making the transference from the dogs on to his parents and in being afraid of the wolf instead of his father. He was in that phase of the development of his attitude towards the world which I have described in *Totem and Taboo* as the return of totemism. The theory which endeavours to explain the primal scenes found in neuroses as retrospective phantasies of a later date seems to obtain powerful support from the present observation, in spite of our patient being of the tender age of four years. Young though he was, he was yet able to succeed in replacing an impression of his fourth year by an imaginary trauma at the age of one and a half. This regression, however, seems neither mysterious nor tendentious. The scene which was to be made up had to fulfil certain conditions which, in consequence of the circumstances of the dreamer's life, could only be found in precisely this early period; such, for instance, was the condition that he should be in bed in his parents' bedroom.

But something that I am able to adduce from the analytic findings in other cases will seem to most readers to be the decisive factor in favour of the correctness of the view here proposed. Scenes of observing sexual intercourse between parents at a very early age (whether they be real memories or phantasies) are as a matter of fact by no means rarities in the analyses of neurotic mortals. Possibly they are no less frequent among those who are not neurotics. Possibly they are part of the regular store in the - conscious or unconscious - treasury of their memories. But as often as I have been able by means of analysis to bring out a scene of this sort, it has shown the same peculiarity which startled us with our present patient too: it has related to *coitus a tergo*, which alone offers the spectator a possibility of inspecting the genitals. There is surely no need any longer to doubt that what we are dealing with is only a phantasy, which is invariably aroused, perhaps, by an observation of the sexual intercourse of animals. And yet more: I have hinted that my description of the 'primal scene' has remained incomplete because I have reserved for a later moment my account of the way in which the child interrupted his parents' intercourse. I must now add that this method of interruption is also the same in every case.

I can well believe that I have now laid myself open to grave aspersions on the part of the readers of this case history. If these arguments in favour of such a view of the 'primal scene' were at my disposal, how could I possibly have taken it on myself to begin by advocating one which seemed so absurd? Or have I made these new observations, which have obliged me to alter my original view, in the interval between the first draft of the case history and this addition, and am I for some reason or other unwilling to admit the fact? I will admit something else instead: I intend on this occasion to close the discussion of the reality of the primal scene with a *non liquet*. This case history is not yet at an end; in its further course a factor will emerge which will shake the certainty which we seem at present to enjoy. Nothing, I think, will then be left but to refer my readers to the passages in my *Introductory Lectures* in which I have treated the problem of primal phantasies or primal scenes.]

VI

THE OBSESSIONAL NEUROSIS

Now for the third time the patient came under a new influence that gave a decisive turn to his development. When he was four and a half years old, and as his state of irritability and apprehensiveness had still not improved, his mother determined to make him acquainted with the Bible story in the hope of distracting and elevating him. Moreover, she succeeded; his initiation into religion brought the previous phase to an end, but at the same time it led to the anxiety symptoms being replaced by obsessional symptoms. Up to then he had not been able to get to sleep easily because he had been afraid of having bad dreams like the one he had had that night before Christmas; now he was obliged before he went to bed to kiss all the holy pictures in the room, to recite prayers, and to make innumerable signs of the cross upon himself and upon his bed.

His childhood now falls clearly into the following epochs: first, the earliest period up to the seduction when he was three and a quarter years old, during which the primal scene took place; secondly, the period of the alteration in his character up to the anxiety dream (four years old); thirdly, the period of the animal phobia up to his initiation into religion (four and a half years old); and from then onwards the period of the obsessional neurosis up to a time later than his tenth year. That there should be an instantaneous and clear-cut displacement of one phase by the next was not in the nature of things or of our patient; on the contrary, the preservation of all that had gone before and the co-existence of the most different sorts of currents were characteristic of him. His naughtiness did not disappear when the anxiety set in, and persisted with slowly diminishing force during the period of piety. But there was no longer any question of a wolf phobia during this last phase. The obsessional neurosis ran its course discontinuously; the first attack was the longest and most intense, and others came on when he was eight and ten, following each time upon exciting causes which stood in a clear relationship to the content of the neurosis.

His mother told him the sacred story herself, and also made his Nanya read aloud to him about it out of a book adorned with illustrations. The chief emphasis in the narrative was naturally laid upon the story of the passion. His Nanya, who was very pious and superstitious, added her own commentary on it, but was also obliged to listen to all the little critic's objections and doubts. If the battles which now began to convulse his mind finally ended in a victory for faith, his Nanya's influence was not without its share in this result.

What he related to me as his recollection of his reactions to this initiation was met by me at first with complete disbelief. It was impossible, I thought, that these could have been the thoughts of a child of four and a half or five; he had probably referred back to this remote past the thoughts which had arisen from the reflections of a grown man of thirty.¹ But the patient would not hear of this correction; I could not succeed, as in so many other differences of opinion between us, in convincing him; and in the end the correspondence between the thoughts which he had recollected and the symptoms of which he gave particulars, as well as the way in which the thoughts fitted into his sexual development, compelled me on the contrary to come to believe him. And I then reflected that this very criticism of the doctrines of religion, which I was unwilling to ascribe to the child, was only achieved by an infinitesimal minority of adults.

I shall now bring forward the material of his recollections, and not until afterwards try to find some path that may lead to an explanation of them.

The impression which he received from the sacred story was, to begin with, as he reported, by no means an agreeable one. He set his face, in the first place, against the feature of suffering in the figure of Christ, and then against his story as a whole. He turned his critical dissatisfaction against God the Father. If he were almighty, then it was his fault that men were wicked and tormented others and were sent to Hell for it. He ought to have made them good; he was responsible himself for all wickedness and all torments. The patient took objection to the command that we should turn the other cheek if our right cheek is smitten, and to the fact that Christ had wished on the Cross that the cup might be taken away from him, as well as to the fact that no miracle had taken place to prove that he was the Son of God. Thus his acuteness was on the alert, and was able to search out with remorseless severity the weak points of the sacred narrative.

¹ I also repeatedly attempted to throw the patient's whole story forward by one year at all events, and in that way to refer the seduction to an age of four and a quarter, the dream to his fifth birthday, etc. As regards the intervals between the events there was no possibility of gaining any time. But the patient remained obdurate on the point, though he did not succeed entirely in removing my doubts. A postponement like this for one year would obviously be of no importance as regards the impression made by his story and as regards the discussion and implications attached to it.

But to this rationalistic criticism there were very soon added ruminations and doubts, which betray to us that hidden impulses were also at work. One of the first questions which he addressed to his Nanya was whether Christ had had a behind too. His Nanya informed him that he had been a god and also a man. As a man he had had and done all the same things as other men. This did not satisfy him at all, but he succeeded in finding consolation of his own by saying to himself that the behind is really only a continuation of the legs. But hardly had he pacified his dread of having to humiliate the sacred figure, when it flared up again as the further question arose whether Christ used to shit too. He did not venture to put this question to his pious Nanya, but he himself found a way out, and she could not have shown him a better. Since Christ had made wine *out of* nothing, he could also have made food *into* nothing and in this way have avoided defaecating.

We shall be in a better position to understand these ruminations if we return to a piece of his sexual development which we have already mentioned. We know that, after the rebuff from his Nanya and the consequent suppression of the beginnings of genital activity, his sexual life developed in the direction of sadism and masochism. He tormented and ill-treated small animals, imagined himself beating horses, and on the other hand imagined the heir to the throne being beaten.¹ In his sadism he maintained his ancient identification with his father; but in his masochism he chose him as a sexual object. He was deep in a phase of the pregenital organization which I regard as the predisposition to obsessional neurosis. The operation of the dream, which brought him under the influence of the primal scene, could have led him to make the advance to the genital organization, and to transform his masochism towards his father into a feminine attitude towards him - into homosexuality. But the dream did not bring about this advance; it ended in a state of anxiety. His relation to his father might have been expected to proceed from the sexual aim of being beaten by him to the next aim, namely, that of being copulated with by him like a woman; but in fact, owing to the opposition of his narcissistic masculinity, this relation was thrown back to an even more primitive stage. It was displaced on to a father-surrogate, and at the same time split off in the shape of a fear of being eaten by the wolf. But this by no means disposed of it. On the contrary, we can only do justice to the apparent complexity of the state of affairs by bearing firmly in mind the co-existence of the three sexual trends which were directed by the boy towards his father. From the time of the dream onwards, in his unconscious he was homosexual, and in his neurosis he was at the level of cannibalism; while the earlier masochistic attitude remained the dominant one. All three currents had passive sexual aims; there was the same object, and the same sexual impulse, but that impulse had become split up along three different levels.

¹ Especially on the penis (see [p. 3517](#)).

His knowledge of the sacred story now gave him a chance of sublimating his predominant masochistic attitude towards his father. He became Christ - which was made specially easy for him on account of their having the same birthday. Thus he became something great and also (a fact upon which enough stress was not laid for the moment) a man. We catch a glimpse of his repressed homosexual attitude in his doubting whether Christ could have a behind, for these ruminations can have had no other meaning but the question whether he himself could be used by his father like a woman - like his mother in the primal scene. When we come to the solution of the other obsessional ideas, we shall find this interpretation confirmed. His reflection that it was insulting to bring the sacred figure into relation with such insinuations corresponded to the repression of his passive homosexuality. It will be noticed that he was endeavouring to keep his new sublimation free from the admixture which it derived from sources in the repressed. But he was unsuccessful.

We do not as yet understand why he also rebelled against the passive character of Christ and against his ill-treatment by his Father, and in this way began also to renounce his previous masochistic ideal, even in its sublimation. We may assume that this second conflict was especially favourable to the emergence of the humiliating obsessional thoughts from the first conflict (between the dominant masochistic and the repressed homosexual currents), for it is only natural that in a mental conflict all the currents upon one side or the other should combine with one another, even though they have the most diverse origins. Some fresh information teaches us the motive of this rebelling and at the same time of the criticisms which he levelled at religion.

His sexual researches, too, gained something from what he was told about the sacred story. So far he had had no reason for supposing that children only came from women. On the contrary, his Nanya had given him to believe that he was his father's child, while his sister was his mother's; and this closer connection with his father had been very precious to him. He now heard that Mary was called the Mother of God. So all children came from women, and what his Nanya had said to him was no longer tenable. Moreover, as a result of what he was told, he was bewildered as to who Christ's father really was. He was inclined to think it we Joseph, as he heard that he and Mary had always lived together, but his Nanya said that Joseph was only 'like' his father and that his real father was God. He could make nothing of that. He only understood this much: if the question was one that could be argued about at all, then the relation between father and son could not be such an intimate one as he had always imagined it to be.

The boy had some kind of inkling of the ambivalent feelings towards the father which are an underlying factor in all religions, and attacked his religion on account of the slackening which it implied in this relation between son and father. Naturally his opposition soon ceased to take the form of doubting the truth of the doctrine, and turned instead directly against the figure of God. God had treated his son harshly and cruelly, but he was no better towards men; he had sacrificed his own son and had ordered Abraham to do the same. He began to fear God.

If he was Christ, then his father was God. But the God which religion forced upon him was not a true substitute for the father whom he had loved and whom he did not want to have stolen from him. His love for this father of his gave him his critical acuteness. He resisted God in order to be able to cling to his father; and in doing this he was really upholding the old father against the new. He was faced by a trying part of the process of detaching himself from his father.

His old love for his father, which had been manifest in his earliest period, was therefore the source of his energy in struggling against God and of his acuteness in criticizing religion. But on the other hand this hostility to the new God was not an original reaction either; it had its prototype in a hostile impulse against his father, which had come into existence under the influence of the anxiety-dream, and it was at bottom only a revival of that impulse. The two opposing currents of feeling, which were to rule the whole of his later life, met here in the ambivalent struggle over the question of religion. It followed, moreover, that what this struggle produced in the shape of symptoms (the blasphemous ideas, the compulsion which came over him of thinking 'God-shit', 'God-swine') were genuine compromise-products, as we shall see from the analysis of these ideas in connection with his anal erotism.

Some other obsessional symptoms of a less typical sort pointed with equal certainty to his father, while at the same time showing the connection between the obsessional neurosis and the earlier occurrences.

A part of the pious ritual by means of which he eventually atoned for his blasphemies was the command to breathe in a ceremonious manner under certain conditions. Each time he made the sign of the cross he was obliged to breathe in deeply or to exhale forcibly. In his native tongue 'breath' is the same word as 'spirit', so that here the Holy Ghost came in. He was obliged to breathe in the Holy Spirit, or to breathe out the evil spirits which he had heard and read about.¹ He ascribed too to these evil spirits the blasphemous thoughts for which he had to inflict such heavy penance upon himself. He was, however, also obliged to exhale when he saw beggars, or cripples, or ugly, old, or wretched-looking people; but he could think of no way of connecting this obsession with the spirits. The only account he could give to himself was that he did it so as not to become like such people.

Eventually, in connection with a dream, the analysis elicited the information that the breathing out at the sight of pitiable-looking people had begun only after his sixth year and was related to his father. He had not seen his father for many months, when one day his mother said she was going to take the children with her to the town and show them something that would very much please them. She then took them to a sanatorium, where they saw their father again; he looked ill, and the boy felt very sorry for him. His father was thus the prototype of all the cripples, beggars, and poor people in whose presence he was obliged to breathe out; just as a father is the prototype of the bogies that people see in anxiety states, and of the caricatures that are drawn to bring derision upon some one. We shall learn elsewhere that this attitude of compassion was derived from a particular detail of the primal scene, a detail which only became operative in the obsessional neurosis at this late moment.

Thus his determination not to become like cripples (which was the motive of his breathing out in their presence) was his old identification with his father transformed into the negative. But in so doing he was also copying his father in the positive sense, for the heavy breathing was an imitation of the noise which he had heard coming from his father during the intercourse.² He had derived the Holy Ghost from this manifestation of male sensual excitement. Repression had turned this breathing into an evil spirit, which had another genealogy as well: namely, the malaria from which he had been suffering at the time of the primal scene.

¹ This symptom, as we shall hear, had developed after his sixth year and when he could already read.

² Assuming the reality of the primal scene.

His repudiation of these evil spirits corresponded to an unmistakable strain of asceticism in him which also found expression in other reactions. When he heard that Christ had once cast out some evil spirits into a herd of swine which then rushed down a precipice, he thought of how his sister in the earliest years of her childhood, before he could remember, had rolled down on to the beach from the cliff-path above the harbour. She too was an evil spirit and a swine. It was a short road from here to 'God-swine'. His father himself had shown that he was no less of a slave to sensuality. When he was told the story of the first of mankind he was struck by the similarity of his lot to Adam's. In conversation with his Nanya he professed hypocritical surprise that Adam should have allowed himself to be dragged into misfortune by a woman, and promised her that he would never marry. A hostility towards women, due to his seduction by his sister, found strong expression at this time. And it was destined to disturb him often enough in his later erotic life. His sister came to be the permanent embodiment for him of temptation and sin. After he had been to confession he seemed to himself pure and free from sin. But then it appeared to him as though his sister were lying in wait to drag him again into sin, and in a moment he had provoked a quarrel with her which made him sinful once more. Thus he was obliged to keep on reproducing the event of his seduction over and over again. Moreover, he had never given away his blasphemous thoughts at confession, in spite of their being such a weight on his mind.

We have been led unawares into a consideration of the symptoms of the later years of the obsessional neurosis; and we shall therefore pass over the occurrences of the intervening period and shall proceed to describe its termination. We already know that, apart from its permanent strength, it underwent occasional intensifications: once - though the episode must for the present remain obscure to us - at the time of the death of a boy living in the same street, with whom he was able to identify himself. When he was ten years old he had a German tutor, who very soon obtained a great influence over him. It is most instructive to observe that the whole of his strict piety dwindled away, never to be revived, after he had noticed and had learnt from enlightening conversations with his tutor that this father surrogate attached no importance to piety and set no store by the truth of religion. His piety sank away along with his dependence upon his father, who was now replaced by a new and more sociable father. This did not take place, however, without one last flicker of the obsessional neurosis; and from this he particularly remembered the obsession of having to think of the Holy Trinity whenever he saw three heaps of dung lying together in the road. In fact he never gave way to fresh ideas without making one last attempt at clinging to what had lost its values for him. When his tutor discouraged him from his cruelties to small animals he did indeed put an end to those misdeeds, but not until he had again cut up caterpillars for a last time to his thorough satisfaction. He still behaved in just the same way during the analytic treatment, for he showed a habit of producing transitory 'negative reactions'; every time something had been conclusively cleared up, he attempted to contradict the effect for a short while by an aggravation of the symptom which had been cleared up. It is quite the rule, as we know, for children to treat prohibitions in the same kind of way. When they have been rebuked for something (for instance, because they are making an unbearable din), they repeat it once more after the prohibition before stopping it. In this way they gain the point of apparently stopping of their own accord and of disobeying the prohibition.

Under the German tutor's influence there arose a new and better sublimation of the patient's sadism which, with the approach of puberty, had then gained the upper hand over his masochism. He developed an enthusiasm for military affairs, for uniforms, weapons and horses, and used them as food for continual day-dreams. Thus, under a man's influence, he had got free from his passive attitudes, and found himself for the time being on fairly normal lines. It was as an after-effect of his affection for the tutor, who left him soon afterwards, that in his later life he preferred German things (as, for instance, physicians, sanatoria, women) to those belonging to his native country (representing his father) - a fact which was incidentally of great advantage to the transference during the treatment.

There was another dream, which belongs to the period before his emancipation by the tutor, and which I mention because it was forgotten until its appearance during the treatment. He saw himself riding on a horse and pursued by a gigantic caterpillar. He recognized in this dream an allusion to an earlier one from the period before the tutor, which we had interpreted long before. In this earlier dream he saw the Devil dressed in black and in the upright posture with which the wolf and the lion had terrified him so much in their day. He was pointing with his out-stretched finger at a gigantic snail. The patient had soon guessed that this Devil was the Demon out of a well-known poem, and that the dream itself was a version of a very popular picture representing the Demon in a love-scene with a girl. The snail was in the woman's place, as being a perfect female sexual symbol. Guided by the Demon's pointing gesture, we were soon able to give as the dream's meaning that the patient was longing for some one who should give him the last pieces of information that were still missing upon the riddle of sexual intercourse, just as his father had given him the first in the primal scene long before.

In connection with the later dream, in which the female symbol was replaced by the male one, he remembered a particular event which had occurred a short time before the dream. Riding on the estate one day, he passed a peasant who was lying asleep with his little boy beside him. The latter woke his father and said something to him, whereupon the father began to abuse the rider and to pursue him till he rode off hastily. There was also a second recollection, that on the same estate there were trees that were quite white, spun all over by caterpillars. We can see that he took flight from the realization of the phantasy of the son lying with his father, and that he brought in the white trees in order to make an allusion to the anxiety dream of the white wolves on the walnut tree. It was thus a direct outbreak of dread of the feminine attitude towards men against which he had at first protected himself by his religious sublimation and was soon to protect himself still more effectively by the military one.

It would, however, be a great mistake to suppose that after the removal of the obsessional symptoms no permanent effects of the obsessional neurosis remained behind. The process had led to a victory for the faith of piety over the rebelliousness of critical research, and had had the repression of the homosexual attitude as its necessary condition. Lasting disadvantages resulted from both these factors. His intellectual activity remained seriously impaired after this first great defeat. He developed no zeal for learning, he showed no more of the acuteness with which at the tender age of five he had criticized and dissected the doctrines of religion. The repression of his over-powerful homosexuality, which was accomplished during the anxiety-dream, reserved that important impulse for the unconscious, kept it directed towards its original aim, and withdrew it from all the sublimations to which it is susceptible in other circumstances. For this reason the patient was without all those social interests which give a content to life. It was only when, during the analytic treatment, it became possible to liberate his shackled homosexuality that this state of affairs showed any improvement; and it was a most remarkable experience to see how (without any direct advice from the physician) each piece of homosexual libido which was set free sought out some application in life and some attachment to the great common concerns of mankind.

VII

ANAL EROTISM AND THE CASTRATION COMPLEX

I must beg the reader to bear in mind that I obtained this history of an infantile neurosis as a by-product, so to speak, during the analysis of an illness in mature years. I have therefore been obliged to put it together from even smaller fragments than are usually at one's disposal for purposes of synthesis. This task, which is not difficult in other respects, finds a natural limit when it is a question of forcing a structure which is itself in many dimensions on to the two-dimensional descriptive plane. I must therefore content myself with bringing forward fragmentary portions, which the reader can then put together into a living whole. The obsessional neurosis that has been described grew up, as has been repeatedly emphasized, on the basis of a sadistic-anal constitution. But we have hitherto discussed only one of the two chief factors - the patient's sadism and its transformations. Everything that concerns his anal erotism has intentionally been left on one side so that it might be brought together and discussed at this later stage.

Analysts have long been agreed that the multifarious instinctual impulses which are comprised under the name of anal erotism play an extraordinarily important part, which it would be quite impossible to over-estimate, in building up sexual life and mental activity in general. It is equally agreed that one of the most important manifestations of the transformed erotism derived from this source is to be found in the treatment of money, for in the course of life this precious material attracts on to itself the psychical interest which was originally proper to faeces, the product of the anal zone. We are accustomed to trace back interest in money, in so far as it is of a libidinal and not of a rational character, to excretory pleasure, and we expect normal people to keep their relations to money entirely free from libidinal influences and regulate them according to the demands of reality.

In our patient, at the time of his later illness, these relations were disturbed to a particularly severe degree, and this fact was not the least considerable element in his lack of independence and his incapacity for dealing with life. He had become very rich through legacies from his father and uncle; it was obvious that he attached great importance to being taken for rich, and he was liable to feel very much hurt if he was undervalued in this respect. But he had no idea how much he possessed, what his expenditure was, or what balance was left over. It was hard to say whether he ought to be called a miser or a spendthrift. He behaved now in this way and now in that, but never in a way that seemed to show any consistent intention. Some striking traits, which I shall further discuss below, might have led one to regard him as a hardened plutocrat, who considered his wealth as his greatest personal advantage, and who would never for a moment allow emotional interests to weigh against pecuniary ones. Yet he did not value other people by their wealth, and, on the contrary, showed himself on many occasions unassuming, helpful, and charitable. Money, in fact, had been withdrawn from his conscious control, and meant for him something quite different.

I have already mentioned that I viewed with grave suspicion the way in which he consoled himself for the loss of his sister, who had become his closest companion during her latter years, with the reflection that now he would not have to share his parents' inheritance with her. But what was perhaps even more striking was the calmness with which he was able to relate this, as though he had no comprehension of the coarseness of feeling to which he was thus confessing. It is true that analysis rehabilitated him by showing that his grief for his sister had merely undergone a displacement; but it then became quite inexplicable why he should have tried to find a substitute for his sister in an increase of wealth.

He himself was puzzled by his behaviour in another connection. After his father's death the property that was left was divided between him and his mother. His mother administered it, and, as he himself admitted, met his pecuniary claims irreproachably and liberally. Yet every discussion of money matters that took place between them used to end with the most violent reproaches on his side, to the effect that she did not love him, that she was trying to economize at his expense, and that she would probably rather see him dead to as so have sole control over the money. His mother used then to protect her disinterestedness with tears, and he would thereupon grow ashamed of himself and declare with justice that he thought nothing of the sort of her. But he was sure to repeat the same scene at the first opportunity.

Many incidents, of which I will relate two, show that, for a long time before the analysis, faeces had had this significance of money for him. At a time when his bowel as yet played no part in his complaint, he once paid a visit to a poor cousin of his in a large town. As he left him he reproached himself for not giving this relative financial support, and immediately afterwards had what was 'perhaps the most urgent need for relieving his bowels that he had experienced in his life'. Two years later he did in fact settle an annuity upon this cousin. Here is the other case. At the age of eighteen, while he was preparing for his leaving-examination at school, he visited a friend and came to an agreement with him on a plan which seemed advisable on account of the dread which they shared of failing in the examination.¹ It had been decided to bribe the school servant, and the patient's share of the sum to be provided was naturally the larger. On the way home he thought to himself that he should be glad to give even more if only he could succeed in getting through, if only he could be sure that nothing would happen to him in the examination - and an accident of another sort really did happen to him ² before he reached his own front door.

We shall be prepared to hear that during his later illness he suffered from disturbances of his intestinal function which were very obstinate, though various circumstances caused them to fluctuate in intensity. When he came under my treatment he had become accustomed to enemas, which were given him by an attendant; spontaneous evacuations did not occur for months at a time, unless a sudden excitement from some particular direction intervened, as a result of which normal activity of the bowels might set in for a few days. His principal subject of complaint was that for him the world was hidden in a veil, or that he was cut off from the world by a veil. This veil was torn only at one moment - when, after an enema, the contents of the bowel left the intestinal canal; and he then felt well and normal again.³

¹ The patient informed me that his native tongue has no parallel to the familiar German use of '*Durchfall*' as a description for disturbance of the bowels.

² This expression has the same meaning in the patient's native tongue as in German.

³ The effect was the same whether he had the enema given him by some one else or whether he managed it himself.

The colleague to whom I referred the patient for a report upon his intestinal condition was perspicacious enough to explain it as being a functional one, or even psychically determined, and to abstain from any active medicinal treatment. Moreover, neither this nor dieting were of any use. During the years of analytic treatment there was no spontaneous motion apart from the sudden influences that I have mentioned. The patient allowed himself to be convinced that if the intractable organ received more intensive treatment things would only be made worse, and contented himself with bringing on an evacuation once or twice a week by means of an enema or a purgative.

In discussing these intestinal troubles I have given more space to the patient's later illness than has been my plan elsewhere in this work, which is concerned with his infantile neurosis. I have done so for two reasons: first, because the intestinal symptoms were in point of fact carried forward from the infantile neurosis into the later one with little alteration, and secondly, because they played a principal part in the conclusion of the treatment.

We know how important doubt is to the physician who is analysing an obsessional neurosis. It is the patient's strongest weapon, the favourite expedient of his resistance. This same doubt enabled our patient to lie entrenched behind a respectful indifference and to allow the efforts of the treatment to slip past him for years together. Nothing changed, and there was no way of convincing him. At last I recognized the importance of the intestinal trouble for my purposes; it represented the small trait of hysteria which is regularly to be found at the root of an obsessional neurosis. I promised the patient a complete recovery of his intestinal activity, and by means of this promise made his incredulity manifest. I then had the satisfaction of seeing his doubt dwindle away, as in the course of the work his bowel began, like a hysterically affected organ, to 'join in the conversation', and in a few week's time recovered its normal functions after their long impairment.

I now turn back to the patient's childhood - to a time at which it was impossible that faeces could have had the significance of money for him.

Intestinal disorders set in very early with him, and especially in the form which is the most frequent and, among children, the most normal - namely, incontinence. We shall certainly be right, however, in rejecting a pathological explanation of these earliest occurrences, and in regarding them only as evidence of the patient's intention not to let himself be disturbed or checked in the pleasure attached to the function of evacuation. He found a great deal of enjoyment (such as would tally with the natural coarseness of many classes of society, though not of his) in anal jokes and exhibitions, and this enjoyment had been retained by him until after the beginning of his later illness.

During the time of the English governess it repeatedly happened that he and his Nanya had to share that obnoxious lady's bedroom. His Nanya noticed with comprehension the fact that precisely on those nights he made a mess in his bed, though otherwise this had ceased to happen a long time before. He was not in the least ashamed of it; it was an expression of defiance against the governess.

A year later (when he was four and a half), during the anxiety period, he happened to make a mess in his knickerbockers in the day-time. He was terribly ashamed of himself, and as he was being cleaned he moaned that he could not go on living like that. So that in the meantime something had changed; and by following up his lament we came upon the traces of this something. It turned out that the words 'he could not go on living like that' were repeated from some one else. His mother had once ¹ taken him with her when she was walking down to the station with the doctor who had come to visit her. During this walk she had lamented over her pains and haemorrhages and had broken out in the same words, 'I cannot go on living like this', without imagining that the child whose hand she was holding would keep them in his memory. Thus his lament (which, moreover, he was to repeat on innumerable occasions during his later illness) had the significance of an identification with his mother.

¹ When this happened was not exactly fixed; but in any case before the anxiety-dream when he was four, and probably before his parents' absence from home.

There soon appeared in his recollection what was evidently, in respect both of its date and of its content, a missing intermediate link between these two events. It once happened at the beginning of his anxiety period that his apprehensive mother gave orders that precautions were to be taken to protect the children from dysentery, which had made its appearance in the neighbourhood of the estate. He made enquiries as to what that might be; and after hearing that when you have dysentery you find blood in your stool he became very nervous and declared that there was blood in his own stool; he was afraid he would die of dysentery, but allowed himself to be convinced by an examination that he had made a mistake and had no need to be frightened. We can see that in this dread he was trying to put into effect an identification with his mother, whose haemorrhages he had heard about in the conversation with her doctor. In his later attempt at identification (when he was four and a half) he had dropped any mention of the blood; he no longer understood himself, for he imagined that he was ashamed of himself and was not aware that he was being shaken by a dread of death, though this was unmistakably revealed in his lament.

At that time his mother, suffering as she was from an abdominal affection, was in general nervous, both about herself and the children; it is most probable that his own nervousness, besides its other motives, was based on an identification with his mother.

Now what can have been the meaning of this identification with his mother?

Between the impudent use he made of his incontinence when he was three and a half, and the horror with which he viewed it when he was four and a half, there lies the dream with which his anxiety period began - the dream which gave him a deferred comprehension of the scene he had experienced when he was one and a half (p. 3533), and an explanation of the part played by women in the sexual act. It is only another step to connect the change in his attitude towards defaecation with this same great revulsion. Dysentery was evidently his name for the illness which he had heard his mother lamenting about, and which it was impossible to go on living with; he did not regard his mother's disease as being abdominal but as being intestinal. Under the influence of the primal scene he came to the conclusion that his mother had been made ill by what his father had done to her;¹ and his dread of having blood in his stool, of being as ill as his mother, was his repudiation of being identified with her in this sexual scene - the same repudiation with which he awoke from the dream. But the dread was also a proof that in his later elaboration of the primal scene he had put himself in his mother's place and had envied her this relation with his father. The organ by which his identification with women, his passive homosexual attitude to men, was able to express itself was the anal zone. The disorders in the function of this zone had acquired the significance of feminine impulses of tenderness, and they retained it during the later illness as well.

At this point we must consider an objection, the discussion of which may contribute much to the elucidation of the apparent confusion of the circumstances. We have been driven to assume that during the process of the dream he understood that women are castrated, that instead of a male organ they have a wound which serves for sexual intercourse, and that castration is the necessary condition of femininity; we have been driven to assume that the threat of this loss induced him to repress his feminine attitude towards men, and that he awoke from his homosexual enthusiasm in anxiety. Now how can this comprehension of sexual intercourse, this recognition of the vagina, be brought into harmony with the selection of the bowel for the purpose of identification with women? Are not the intestinal symptoms based on what is probably an older notion, and one which in any case completely contradicts the dread of castration - the notion, namely, that sexual intercourse takes place at the anus?

To be sure, this contradiction is present; and the two views are entirely inconsistent with each other. The only question is whether they need be consistent. Our bewilderment arises only because we are always inclined to treat unconscious mental processes like conscious ones and to forget the profound differences between the two psychical systems.

¹ A conclusion which was probably not far from the truth.

When his Christmas dream, with its excitement and expectancy, conjured up before him the picture of the sexual intercourse of his parents as it had once been observed (or construed) by him, there can be no doubt that the first view of it to come up was the old one, according to which the part of the female body which received the male organ was the anus. And, indeed, what else could he have supposed when at the age of one and a half he was a spectator of the scene?¹ But now came the new event that occurred when he was four years old. What he had learnt in the meantime, the allusions which he had heard to castration, awoke and cast a doubt on the 'cloacal theory'; they brought to his notice the difference between the sexes and the sexual part played by women. In this contingency he behaved as children in general behave when they are given an unwished for piece of information - whether sexual or of any other kind. He rejected what was new (in our case from motives connected with his fear of castration) and clung fast to what was old. He decided in favour of the intestine and against the vagina, just as, for similar motives, he later on took his father's side against God. He rejected the new information and clung to the old theory. The latter must have provided the material for his identification with women, which made its appearance later as a dread of death in connection with the bowels, and for his first religious scruples, about whether Christ had had a behind, and so on. It is not that his new insight remained without any effect; quite the reverse. It developed an extraordinarily powerful effect, for it became a motive for keeping the whole process of the dream under repression and for excluding it from being worked over later in consciousness. But with that its effect was exhausted; it had no influence in deciding the sexual problem. That it should have been possible from that time onwards for a fear of castration to exist side by side with an identification with women by means of the bowel admittedly involved a contradiction. But it was only a logical contradiction - which is not saying much. On the contrary, the whole process is characteristic of the way in which the unconscious works. A repression is something very different from a condemning judgement.

¹ Or so long as he did not grasp the sense of the copulation between the dogs.

When we were studying the genesis of the wolf phobia, we followed the effect of his new insight into the sexual act; but now that we are investigating the disturbances of the intestinal function, we find ourselves working on the basis of the old cloacal theory. The two points of view remained separated from each other by a stage of repression. His feminine attitude towards men, which had been repudiated by the act of repression, drew back, as it were, into the intestinal symptoms, and expressed itself in the attacks of diarrhoea, constipation, and intestinal pain, which were so frequent during the patient's childhood. His later sexual phantasies, which were based on a correct sexual knowledge, were thus able to express themselves regressively as intestinal troubles. But we cannot understand them until we have explained the modifications which take place in the significance of faeces from the first years of childhood onward.¹

I have already hinted at an earlier point in my story that one portion of the content of the primal scene has been kept back. I am now in a position to produce this missing portion. The child finally interrupted his parents' intercourse by passing a stool, which gave him an excuse for screaming. All the considerations which I have raised above in discussing the rest of the content of the same scene apply equally to the criticism of this additional piece. The patient accepted this concluding act when I had constructed it, and appeared to confirm it by producing 'transitory symptoms'. A further additional piece which I had proposed, to the effect that his father was annoyed at the interruption and gave vent to his ill-humour by scolding him, had to be dropped. The material of the analysis did not react to it.

The additional detail which I have now brought forward cannot of course be put on a level with the rest of the content of the scene. Here it is not a question of an impression from outside, which must be expected to re-emerge in a number of later indications, but of a reaction on the part of the child himself. It would make no difference to the story as a whole if this demonstration had not occurred, or if it had been taken from a later period and inserted into the course of the scene. But there can be no question of how we are to regard it. It is a sign of a state of excitement of the anal zone (in the widest sense). In other similar cases an observation like this of sexual intercourse has ended with a discharge of urine; a grown-up man in the same circumstances would feel an erection. The fact that our little boy passed a stool as a sign of his sexual excitement is to be regarded as a characteristic of his congenital sexual constitution. He at once assumed a passive attitude, and showed more inclination towards a subsequent identification with women than with men.

¹ Cf. 'On Transformations of Instinct as Exemplified in Anal Erotism' (1917c).

At the same time, like every other child, he was making use of the content of the intestines in one of its earliest and most primitive meanings. Faeces are the child's first *gift*, the first sacrifice on behalf of his affection, a portion of his own body which he is ready to part with, but only for the sake of some one he loves.¹ To use faeces as an expression of defiance, as our patient did against the governess when he was three and a half, is merely to turn this earlier 'gift' meaning into the negative. The '*grumus merdae*' [heap of faeces] left behind by criminals upon the scene of their misdeeds seems to have both these meanings: contumely, and a regressive expression of making amends. It is always possible, when a higher stage has been reached, for use still to be made of the lower one in its negative and debased sense. The contrariety is a manifestation of repression.²

¹ I believe there can be no difficulty in substantiating the statement that infants only soil with their excrement people whom they know and are fond of; they do not consider strangers worthy of this distinction. In my *Three Essays on the Theory of Sexuality* (1905d) I mentioned the very first purpose to which faeces are put - namely, the auto-erotic stimulation of the intestinal mucous membrane. We now reach a further stage, at which a decisive part in the process of defaecation is played by the child's attitude to some object to whom he thus shows himself obedient or agreeable. This relation is one that persists; for even older children will only allow themselves to be assisted in defaecating and urinating by particular privileged persons, though in this connection the prospect of other forms of satisfaction is also involved.

² In the unconscious, as we are aware, 'No' does not exist, and there is no distinction between contraries. Negation is only introduced by the process of repression.

At a later stage of sexual development faeces take on the meaning of a *baby*. For babies, like faeces, are born through the anus. The 'gift' meaning of faeces readily admits of this transformation. It is a common usage to speak of a baby as a 'gift'. The more frequent expression is that the woman has 'given' the man a baby; but in the usage of the unconscious equal attention is justly paid to the other aspect of the relation, namely, to the woman having 'received' the baby as a gift from the man.

The meaning of faeces as *money* branches off from the 'gift' meaning in another direction.

The deeper significance of our patient's early screen memory, to the effect that he had his first fit of rage because he was not given enough presents one Christmas, is now revealed to us. What he was feeling the want of was sexual satisfaction, which he had taken as being anal. His sexual researches came during the course of the dream to understand what they had been prepared for finding before the dream, namely, that the sexual act solved the problem of the origin of babies. Even before the dream he had disliked babies. Once, when he had come upon a small unfledged bird that had fallen out of its nest, he had taken it for a human baby and been horrified at it. The analysis showed that all small animals, such as caterpillars and insects, that he had been so enraged with, had had the meaning of babies to him.¹ His position in regard to his elder sister had given him every opportunity for reflecting upon the relation between elder and younger children. His Nanya had once told him that his mother was so fond of him because he was the youngest, and this gave him good grounds for wishing that no younger child might come after him. His dread of this youngest child was revived under the influence of the dream which brought up before him his parents' intercourse.

To the sexual currents that are already known to us we must therefore add a further one, which, like the rest, started from the primal scene reproduced in the dream. In his identification with women (that is, with his mother) he was ready to give his father a baby, and was jealous of his mother, who had already done so and would perhaps do so again.

¹ Just as vermin often stands for babies in dreams and phobias.

In a roundabout way, since both 'money' and 'baby' have the sense of 'gift', money can take over the meaning of baby and can thus become the means of expressing feminine (homosexual) satisfaction. This was what occurred with our patient when - he and his sister were staying at a German sanatorium at the time - he saw his father give his sister two large bank notes. In imagination he had always had suspicions of his father's relations with his sister; and at this his jealousy awoke. He rushed at his sister as soon as they were alone, and demanded a share of the money with so much vehemence and such reproaches that his sister, in tears, threw him the whole of it. What had excited him was not merely the actual money, but rather the 'baby' - anal sexual satisfaction from his father. And he was able to console himself with this when, in his father's lifetime, his sister died. The revolting thought which occurred to him when he heard the news of her death in fact meant no more than this: 'Now I am the only child. Now Father will have to love me only.' But though his reflection was in itself perfectly capable of becoming conscious, yet its homosexual background was so intolerable that it was possible for its disguise in the shape of the most sordid avarice to come as a great relief.

Similarly, too, when after his father's death he reproached his mother so unjustifiably with wanting to cheat him out of the money and with being fonder of the money than of him. His old jealousy of her for having loved another child besides him, the possibility of her having wanted another child after him, drove him into making charges which he himself knew were unwarranted.

This analysis of the meaning of faeces makes it clear that the obsessive thoughts which obliged him to connect God with faeces had a further significance beyond the disparagement which he saw in them himself. They were in fact true compromise-products, in which a part was played no less by an affectionate current of devotion than by a hostile current of abuse. 'God-shit' was probably an abbreviation for an offering that one occasionally hears mentioned in its unabbreviated form. 'Shitting on God' [*auf Gott scheissen*] or 'shitting something for God' [*Gott etwas scheissen*] also means giving him a baby or getting him to give one a baby. The old 'gift' meaning in its negative and debased form and the 'baby' meaning that was later developed from it are combined with each other in the obsessional phrase. In the latter of these meanings a feminine tenderness finds expression: a readiness to give up one's masculinity if in exchange for it one can be loved like a woman. Here, then, we have precisely the same impulse towards God which was expressed in unambiguous words in the delusional system of the paranoic *Senatspräsident* Schreber.

When later on I come to describing the final clearing up of my patient's symptoms, the way in which the intestinal disorder had put itself at the service of the homosexual current and had given expression to his feminine attitude towards his father will once again become evident. Meanwhile we shall mention a further meaning of faeces, which will lead us on to a discussion of the castration complex.

Since the column of faeces stimulates the erotogenic mucous membrane of the bowel, it plays the part of an active organ in regard to it; it behaves just as the penis does to the vaginal mucous membrane, and acts as it were as its forerunner during the cloacal epoch. The handing over of faeces for the sake of (out of love for) some one else becomes a prototype of castration; it is the first occasion upon which an individual parts with a piece of his own body ¹ in order to gain the favour of some other person whom he loves. So that a person's love of his own penis, which is in other respects narcissistic, is not without an element of anal erotism. 'Faeces', 'baby' and 'penis' thus form a unity, an unconscious concept (*sit venia verbo*) - the concept, namely, of 'a little one' that can become separated from one's body. Along these paths of association the libidinal cathexis may become displaced or intensified in ways which are pathologically important and which are revealed by analysis.

We are already acquainted with the attitude which our patient first adopted to the problem of castration. He rejected castration, and held to his theory of intercourse by the anus. When I speak of his having rejected it, the first meaning of the phrase is that he would have nothing to do with it, in the sense of having repressed it. This really involved no judgement upon the question of its existence, but it was the same as if it did not exist. Such an attitude, however, could not have been his final one, even at the time of his infantile neurosis. We find good subsequent evidence of his having recognized castration as a fact. In this connection, once again, he behaved in the manner which was so characteristic of him, but which makes it so difficult to give a clear account of his mental processes or to feel one's way into them. First he resisted and then he yielded; but the second reaction did not *do away with* the first. In the end there were to be found in him two contrary currents side by side, of which one abominated the idea of castration, while the other was prepared to accept it and console itself with femininity as a compensation. But beyond any doubt a third current, the oldest and deepest, which did not as yet even raise the question of the reality of castration, was still capable of coming into activity. I have elsewhere ² reported a hallucination which this same patient had at the age of five and upon which I need only add a brief commentary here.

¹ It is as such that faeces are invariably treated by children.

² '*Fausse Reconnaissance* ("Déjà Raconté") in *Psycho-Analytic Treatment*' (1914a).

"When I was five years old, I was playing in the garden near my nurse, and was carving with my pocket-knife in the bark of one of the walnut-trees that come into my dream as well.¹ Suddenly, to my unspeakable terror, I noticed that I had cut through the little finger of my (right or left?) hand, so that it was only hanging on by its skin. I felt no pain, but great fear. I did not venture to say anything to my nurse, who was only a few paces distant, but I sank down on the nearest seat and sat there incapable of casting another glance at my finger. At last I calmed down, took a look at the finger, and saw that it was entirely uninjured."

After he had received his instruction in the Bible story at the age of four and a half he began, as we know, to make the intense effort of thought which ended in his obsessional piety. We may therefore assume that this hallucination belongs to the period in which he brought himself to recognize the reality of castration and it is perhaps to be regarded as actually marking this step. Even the small correction made by the patient is not without interest. If he had a hallucination of the same dreadful experience which Tasso, in his *Gerusalemme Liberata*, tells of his hero Tancred, we shall perhaps be justified in reaching the interpretation that the tree meant a woman to my little patient as well. Here, then, he was playing the part of his father, and was connecting his mother's familiar haemorrhages with the castration of women, which he now recognized, - with the 'wound'.

¹ 'Cf. "The Occurrence in Dreams of Material from Fairy Tales". In telling the story again on a later occasion he made the following correction: "I don't believe I was cutting the tree. That was a confusion with another recollection, which must also have been hallucinatorily falsified, of having made a cut in a tree with my knife and of *blood* having come out of the tree."

His hallucination of the severed finger was instigated, as he reported later on, by the story that a female relation of his had been born with six toes and that the extra one had immediately afterwards been chopped off with an axe. Women, then, had no penis because it was taken away from them at birth. In this manner he came, at the period of the obsessional neurosis, to accept what he had already learned during the dream but had at the time rejected by repression. He must also have become acquainted, during the readings and discussions of the sacred story, with the ritual circumcision of Christ and of the Jews in general.

There is no doubt whatever that at this time his father was turning into the terrifying figure that threatened him with castration. The cruel God with whom he was then struggling - who made men sinful, only to punish them afterwards, who sacrificed his own son and the sons of men - this God threw back his character on to the patient's father, though, on the other hand, the boy was at the same time trying to defend his father against the God. At this point the boy had to fit into a phylogenetic pattern, and he did so, although his personal experiences may not have agreed with it. Although the threats or hints of castration which had come his way had emanated from women,¹ this could not hold up the final result for long. In spite of everything it was his father from whom in the end he came to fear castration. In this respect heredity triumphed over accidental experience; in man's prehistory it was unquestionably the father who practised castration as a punishment and who later softened it down into circumcision. The further the patient went in repressing sensuality during the course of the development of the obsessional neurosis,² the more natural it must have become to him to attribute these evil intentions to his father, who was the true representative of sensual activity.

¹ We already know this as regards his Nanya; and we shall hear of it again in connection with another woman.

² For evidence of this see p. 3551.

His identification of his father with the castrator ¹ became important as being the source of an intense unconscious hostility towards him (which reached the pitch of a death-wish) and of a sense of guilt which reacted against it. Up to this point, however, he was behaving normally - that is to say, like every neurotic who is possessed by a positive Oedipus complex. But the astonishing thing was that even against this there was a counter-current working in him, which, on the contrary, regarded his father as the one who had been castrated and as calling, therefore, for his sympathy.

When I analysed his ceremonial of breathing out whenever he saw cripples, beggars, and such people, I was able to show that that symptom could also be traced back to his father, whom he had felt sorry for when he visited him as a patient in the sanatorium. The analysis made it possible to follow this thread even further back. At a very early period, probably before his seduction (at the age of three and a quarter), there had been on the estate an old day-labourer whose business it was to carry the water into the house. He could not speak, ostensibly because his tongue had been cut out. (He was probably a deaf mute.) The little boy was very fond of him and pitied him deeply. When he died, he looked for him in the sky.² Here, then, was the first of the cripples for whom he had felt sympathy, and, as was shown by the context and the point at which the episode came out in the analysis, an undoubted father-surrogate.

¹ Among the most tormenting, though at the same time the most grotesque, symptoms of his later illness was his relation to every tailor from whom he ordered a suit of clothes: his deference and timidity in the presence of this high functionary, his attempts to get into his good books by giving him extravagant tips, and his despair over the results of the work however it might in fact have turned out.

² In this connection I may mention some dreams which he had, later than the anxiety-dream, but while he was still on the first estate. These dreams represented the scene of coition as an event taking place between heavenly bodies.

In the analysis this man was associated with the recollection of other servants whom the patient had liked and about whom he emphasized the fact that they had been either sickly or Jews (which implied circumcision). The footman, too, who had helped to clean him after his accident at four and a half, had been a Jew and a consumptive and had been an object of his compassion. All of these figures belong to the period before his visit to his father at the sanatorium, that is, before the formation of the symptom; the latter must therefore rather have been intended to ward off (by means of the breathing out) any identification with the object of the patient's pity. Then suddenly, in connection with a dream, the analysis plunged back into the prehistoric period, and led him to assert that during the copulation in the primal scene he had observed the penis disappear, that he had felt compassion for his father on that account, and had rejoiced at the reappearance of what he thought had been lost. So here was a fresh emotional impulse, starting once again from the primal scene. Moreover, the narcissistic origin of compassion (which is confirmed by the word itself) is here quite unmistakably revealed.

VIII

FRESH MATERIAL FROM THE PRIMAL PERIOD - SOLUTION

It happens in many analyses that as one approaches their end new recollections emerge which have hitherto been kept carefully concealed. Or it may be that on one occasion some unpretentious remark is thrown out in an indifferent tone of voice as though it were superfluous; that then, on another occasion, something further is added, which begins to make the physician prick his ears; and that at last he comes to recognize this despised fragment of a memory as the key to the weightiest secrets that the patient's neurosis has veiled.

Early in the analysis my patient had told me of a memory of the period in which his naughtiness had been in the habit of suddenly turning into anxiety. He was chasing a beautiful big butterfly with yellow stripes and large wings which ended in pointed projections - a swallow-tail, in fact. Suddenly, when the butterfly had settled on a flower, he was seized with a dreadful fear of the creature, and ran away screaming.

This memory recurred occasionally during the analysis, and called for an explanation; but for a long time none was to be found. Nevertheless it was to be assumed as a matter of course that a detail like this had not kept its place in his recollection on its own account, but that it was a screen-memory, representing something of more importance with which it was in some way connected. One day he told me that in his language a butterfly was called '*babushka*', 'granny'. He added that in general butterflies had seemed to him like women and girls, and beetles and caterpillars like boys. So there could be little doubt that in this anxiety scene a recollection of some female person had been aroused. I will not hide the fact that at that time I put forward the possibility that the yellow stripes on the butterfly had reminded him of similar stripes on a piece of clothing worn by some woman. I only mention this as an illustration to show how inadequate the physician's constructive efforts usually are for clearing up questions that arise, and how unjust it is to attribute the results of analysis to the physician imagination and suggestion.

Many months later, in quite another connection, the patient remarked that the opening and shutting of the butterfly's wings while it was settled on the flower had given him an uncanny feeling. It had looked, so he said, like a woman opening her legs, and the legs then made the shape of a Roman V, which, as we know, was the hour at which, in his boyhood, and even up to the time of the treatment, he used to fall into a depressed state of mind.

This was an association which I could never have arrived at myself, and which gained importance from a consideration of the thoroughly infantile nature of the train of association which it revealed. The attention of children, as I have often noticed, is attracted far more readily by movements than by forms at rest; and they frequently base associations upon a similarity of movement which is overlooked or neglected by adults.

After this the little problem was once more left untouched for a long time; but I may mention the facile suspicion that the points or stick-like projections of the butterfly's wings might have had the meaning of genital symbols.

One day there emerged, timidly and indistinctly, a kind of recollection that at a very early age, even before the time of the nurse, he must have had a nursery-maid who was very fond of him. Her name had been the same as his mother's. He had no doubt returned her affection. It was, in fact, a first love that had faded into oblivion. But we agreed that something must have occurred at that time that became of importance later on.

Then on another occasion he emended this recollection. She could not have had the same name as his mother; that had been a mistake on his part, and it showed, of course, that in his memory she had become fused with his mother. Her real name, he went on, had occurred to him in a roundabout way. He had suddenly thought of a store-room, on the first estate, in which fruit was kept after it had been picked, and of a particular sort of pear with a most delicious taste - a big pear with yellow stripes on its skin. The word for 'pear' in his language was '*grusha*', and that had also been the name of the nursery-maid.

It thus became clear that behind the screen memory of the hunted butterfly the memory of the nursery-maid lay concealed. But the yellow stripes were not on her dress, but on the pear whose name was the same as hers. What, however, was the origin of the anxiety which had arisen when the memory of her had been activated? The obvious answer to this might have been the crude hypothesis that it had been this girl whom, when he was a small child, he had first seen making the movements with her legs which he had fixed in his mind with the Roman V - movements which allow access to the genitals. We spared ourselves such theorizing as this and waited for more material.

Very soon after this there came the recollection of a scene, incomplete, but, so far as it was preserved, definite. Grusha was kneeling on the floor, and beside her a pail and a short broom made of a bundle of twigs; he was also there, and she was teasing him or scolding him.

The missing elements could easily be supplied from other directions. During the first months of the treatment he had told me of how he had suddenly fallen in love in a compulsive manner with a peasant girl from whom, in his eighteenth year, he had contracted the precipitating cause of his later illness. When he told me this he had displayed a most extraordinary unwillingness to give me the girl's name. It was an entirely isolated instance of resistance, for apart from it he obeyed the fundamental rule of analysis unreservedly. He asserted, however, that the reason for his being so much ashamed of mentioning the name was that it was a purely peasant name and that no girl of gentle birth could possibly be called by it. When eventually the name was produced, it turned out to be Matrona, which has a motherly ring about it. The shame was evidently displaced. He was not ashamed of the fact that these love-affairs were invariably concerned with girls of the humblest origin; he was ashamed only of the name. If it should turn out that the affair with Matrona had something in common with the Grusha scene, then the shame would have to be transferred back to that early episode.

He had told me another time that when he heard the story of John Huss he had been greatly moved, and that his attention had been held by the bundles of firewood that were dragged up when he was burnt at the stake. Now his sympathy for Huss created a perfectly definite suspicion in my mind, for I have often come upon this sympathy in youthful patients and I have always been able to explain it in the same way. One such patient even went so far as to produce a dramatized version of Huss's career; he began to write his play on the day on which he lost the object with whom he was secretly in love. Huss perished by fire, and (like others who possess the same qualification) he becomes the hero of people who have at one time suffered from enuresis. My patient himself connected the bundles of firewood used for the execution of Huss with the nursery-maid's broom or bundle of twigs.

This material fitted together spontaneously and served to fill in the gaps in the patient's memory of the scene with Grusha. When he saw the girl scrubbing the floor he had micturated in the room and she had rejoined, no doubt jokingly, with a threat of castration.¹

I do not know if my readers will have already guessed why it is that I have given such a detailed account of this episode from the patient's early childhood.² It provides an important link between the primal scene and the later compulsive love which came to be of such decisive significance in his subsequent career, and it further shows us a condition upon which his falling in love depended and which elucidates that compulsion.

When he saw the girl on the floor engaged in scrubbing it, and kneeling down, with her buttocks projecting and her back horizontal, he was faced once again with the posture which his mother had assumed in the copulation scene. She became his mother to him; he was seized with sexual excitement owing to the activation of this picture;³ and, like his father (whose action he can only have regarded at the time as micturition), he behaved in a masculine way towards her. His micturition on the floor was in reality an attempt at a seduction, and the girl replied to it with a threat of castration, just as though she had understood what he meant.

¹ It is very remarkable that the reaction of shame should be so intimately connected with involuntary emptying of the bladder (whether in the day-time or at night) and not equally so, as one would have expected, with incontinence of the bowels. Experience leaves no room for doubt upon the point. The regular relation that is found to exist between incontinence of the bladder and fire also provides matter for reflection. It is possible that these reactions and relations represent precipitates from the history of human civilization derived from a lower stratum than anything that is preserved for us in the traces surviving in myths or folklore.

² It may be assigned to a time at which he was about two and a half: between his supposed observation of intercourse and his seduction.

³ This was *before* the dream.

The compulsion which proceeded from the primal scene was transferred on to this scene with Grusha and was carried forward by it. But the condition upon which his falling in love depended underwent a change which showed the influence of the second scene: it was transferred from the woman's posture to the occupation on which she was engaged while in that posture. This was clear, for instance, in the episode of Matrona. He was walking through the village which formed part of their (later) estate, when he saw a peasant girl kneeling by the pond and employed in washing clothes in it. He fell in love with the girl instantly and with irresistible violence, although he had not yet been able to get even a glimpse of her face. By her posture and occupation she had taken the place of Grusha for him. We can now see now it was that the shame which properly related to the content of the scene with Grusha could become attached to the name of Matrona.

Another attack of falling in love, dating from a few years earlier, shows even more clearly the compelling influence of the Grusha scene. A young peasant girl, who was a servant in the house, had long attracted him, but he succeeded in keeping himself from approaching her. One day, when he came upon her in a room by herself, he was overwhelmed by his love. He found her kneeling on the floor and engaged in scrubbing it, with a pail and a broom beside her - in fact, exactly as he had seen the girl in his childhood.

Even his final choice of object, which played such an important part in his life, is shown by its details (though they cannot be adduced here) to have been dependent upon the same condition and to have been an offshoot of the compulsion which, starting from the primal scene and going on to the scene with Grusha, had dominated his love-choice. I have remarked on an earlier page that I recognize in the patient an endeavour to debase his love-object. This is to be explained as a reaction against pressure from the sister who was so much his superior. But I promised at the same time (see p. 3515) to show that this self-assertive motive was not the only determinant, but that it concealed another and deeper one based on purely erotic motives. These were brought to light by the patient's memory of the nursery-maid scrubbing the floor - *physically* debased too, by the by. All his later love-objects were surrogates for this one person, who through the accident of her attitude had herself become his first mother-surrogate. The patient's first association in connection with the problem of his fear of the butterfly can now easily be explained retrospectively as a distant allusion to the primal scene (the hour of five). He confirmed the connection between the Grusha scene and the threat of castration by a particularly ingenious dream, which he himself succeeded in deciphering. 'I had a dream,' he said, 'of a man tearing off the wings of an *Espe*.' '*Espe*?' I asked; 'what do you mean by that?' 'You know; that insect with yellow stripes on its body, that stings.' I could now put him right: 'So what you mean is a *Wespe* [wasp].' 'Is it called a *Wespe*? I really thought it was called an *Espe*.' (Like so many other people, he used his difficulties with a foreign language as a screen for symptomatic acts.) 'But *Espe*, why, that's myself: S. P.' (which were his initials). The *Espe* was of course a mutilated *Wespe*. The dream said clearly that he was avenging himself on Grusha for her threat of castration.

The action of the two-and-a-half-year-old boy in the scene with Grusha is the earliest effect of the primal scene which has come to our knowledge. It represents him as copying his father, and shows us a tendency towards development in a direction which would later deserve the name of masculine. His seduction drove him into passivity - for which, in any case, the way was prepared by his behaviour when he was a witness of his parents' intercourse.

I must here turn for a moment to the history of the treatment. When once the Grusha scene had been assimilated - the first experience that he could really remember, and one which he had remembered without any conjectures or intervention on my part - the problem of the treatment had every appearance of having been solved. From that time forward there were no more resistances; all that remained to be done was to collect and to co-ordinate. The old trauma theory of the neuroses, which was after all built up upon impressions gained from psycho-analytic practice, had suddenly come to the front once more. Out of critical interest I made one more attempt to force upon the patient another view of his story, which might commend itself more to sober common sense. It was true that there could be no doubt about the scene with Grusha, but, I suggested, in itself that scene meant nothing; it had been emphasized *ex post facto* by a regression from the circumstances of his object choice, which, as a result of his intention to debase, had been diverted from his sister on to servant girls. On the other hand, his observation of intercourse, I argued, was a phantasy of his later years; its historical nucleus may perhaps have been an observation or an experience by the patient of the administration of an innocent enema. Some of my readers will possibly be inclined to think that with such hypotheses as these I was for the first time beginning to approach an understanding of the case; but the patient looked at me uncomprehendingly and a little contemptuously when I put this view before him, and he never reacted to it again. I have already stated my own arguments against any such rationalization at their proper point in the discussion.

[Thus ¹ the Grusha scene, by explaining the conditions governing the patient's object-choice - conditions which were of decisive importance in his life - prevents our over-estimating the significance of his intention to debase women. But it does more than this. It affords me a justification for having refused on an earlier page (see p. 3545) to adopt unhesitatingly, as the only tenable explanation, the view that the primal scene was derived from an observation made upon animals shortly before the dream. The Grusha scene emerged in the patient's memory spontaneously and through no effort of mine. His fear of the yellow-striped butterfly, which went back to that scene, proved that the scene had had a significant content, or that he had been able to attach this significance to its content subsequently. By means of the accompanying associations and the inferences that followed from them, it was possible with certainty to supply this significant element which was lacking in the patient's memory. It then appeared that his fear of the butterfly was in every respect analogous to his fear of the wolf; in both cases it was a fear of castration, which was, to begin with, referred to the person who had first uttered the threat of castration, but was then transposed on to another person to whom it was bound to become attached in accordance with phylogenetic precedent. The scene with Grusha had occurred when the patient was two and a half, but the anxiety-episode with the yellow butterfly was certainly subsequent to the anxiety-dream. It was easy to understand how the patient's later comprehension of the possibility of castration had retrospectively brought out the anxiety in the scene with Grusha. But that scene in itself contained nothing objectionable or improbable; on the contrary, it consisted entirely of commonplace details which gave no grounds for scepticism. There was nothing in it which could lead one to attribute its origin to the child's imagination; such a supposition, indeed, seemed scarcely possible.

¹ [Freud's square brackets.]

The question now arises whether we are justified in regarding the fact that the boy micturated, while he stood looking at the girl on her knees scrubbing the floor, as a proof of sexual excitement on his part. If so, the excitement would be evidence of the influence of an earlier impression, which might equally have been the actual occurrence of the primal scene or an observation made upon animals before the age of two and a half. Or are we to conclude that the situation as regards Grusha was entirely innocent, that the child's emptying his bladder was purely accidental, and that it was not until later that the whole scene became sexualized in his memory, after he had come to recognize the importance of similar situations?

On these issues I can venture upon no decision. I must confess, however, that I regard it as greatly to the credit of psycho-analysis that it should even have reached the stage of *raising* such questions as these. Nevertheless, I cannot deny that the scene with Grusha, the part it played in the analysis, and the effects that followed from it in the patient's life can be most naturally and completely explained if we consider that the primal scene, which may in other cases be a phantasy, was a reality in the present one. After all, there is nothing impossible about it; and the hypothesis of its reality is entirely compatible with the inciting action of the observations upon animals which are indicated by the sheep-dogs in the dream-picture.

I will now turn from this unsatisfactory conclusion to a consideration of the problem which I have attempted in my *Introductory Lectures on Psycho-Analysis*. I should myself be glad to know whether the primal scene in my present patient's case was a phantasy or a real experience; but, taking other similar cases into account, I must admit that the answer to this question is not in fact a matter of very great importance. These scenes of observing parental intercourse, of being seduced in childhood, and of being threatened with castration are unquestionably an inherited endowment, a phylogenetic heritage, but they may just as easily be acquired by personal experience. With my patient, his seduction by his elder sister was an indisputable reality; why should not the same have been true of his observation of his parents' intercourse?

All that we find in the prehistory of neuroses is that a child catches hold of this phylogenetic experience where his own experience fails him. He fills in the gaps in individual truth with prehistoric truth; he replaces occurrences in his own life by occurrences in the life of his ancestors. I fully agree with Jung ¹ in recognizing the existence of this phylogenetic heritage; but I regard it as a methodological error to seize on a phylogenetic explanation before the ontogenetic possibilities have been exhausted. I cannot see any reason for obstinately disputing the importance of infantile prehistory while at the same time freely acknowledging the importance of ancestral prehistory. Nor can I overlook the fact that phylogenetic motives and productions themselves stand in need of elucidation, and that in quite a number of instances this is afforded by factors in the childhood of the individual. And, finally, I cannot feel surprised that what was originally produced by certain circumstances in prehistoric times and was then transmitted in the shape of a predisposition to its re-acquirement should, since the same circumstances persist, emerge once more as a concrete event in the experience of the individual.]

¹ *Die Psychologie der unbewussten Prozesse*, 1917. This was published too late for it to have influenced my *Introductory Lectures*.

Room must also be found in the interval between the primal scene and the seduction (from the age of one and a half to the age of three and a quarter) for the dumb water-carrier. He served the patient as a father-surrogate just as Grusha served him as a mother-surrogate. I do not think there is any justification for regarding this as an example of the intention to debase, even though it is true that both parents have come to be represented by servants. A child pays no regard to social distinctions, which have little meaning for him as yet; and he classes people of inferior rank with his parents if such people love him as his parents do. Nor is the intention to debase any more responsible for the substitution of animals for a child's parents, for children are very far indeed from taking a disparaging view of animals. Uncles and aunts are used as parent-surrogates without any regard to the question of debasing, and this was in fact done by our present patient, as many of his recollections showed.

There also belongs in this period a phase, which was obscurely remembered, in which he would not eat anything except sweet things, until alarm was felt on the score of his health. He was told about one of his uncles who had refused to eat in the same way and had wasted away to death while he was still young. He was also informed that when he himself was three months old he had been so seriously ill (with pneumonia?) that his winding-sheet had been got ready for him. In this way they succeeded in alarming him, so that he began eating again; and in the later years of his childhood he used actually to overdo this duty, as though to guard himself against the threat of death. The fear of death, which was evoked at that time for his own protection, made its reappearance later when his mother warned him of the danger of dysentery. Later still, it brought on an attack of his obsessional neurosis (see [p. 3551](#)). We shall try below to go into its origins and meanings.

I am inclined to the opinion that this disturbance of appetite should be regarded as the very first of the patient's neurotic illnesses. If so, the disturbance of appetite, the wolf phobia, and the obsessional piety would constitute the complete series of infantile disorders which laid down the predisposition for his neurotic break-down after he had passed the age of puberty. It will be objected that few children escape such disorders as a temporary loss of appetite or an animal phobia. But this argument is exactly what I should wish for. I am ready to assert that every neurosis in an adult is built upon a neurosis which has occurred in his childhood but has not invariably been severe enough to strike the eye and be recognized as such. This objection only serves to emphasize the theoretical importance of the part which infantile neuroses must play in our view of those later disorders which we treat as neuroses and endeavour to attribute entirely to the effects of adult life. If our present patient had not suffered from obsessional piety in addition to his disturbance of appetite and his animal phobia, his story would not have been noticeably different from that of other children, and we should have been the poorer by the loss of precious material which may guard us against certain plausible errors.

The analysis would be unsatisfactory if it failed to explain the phrase used by the patient for summing up the troubles of which he complained. The world, he said, was hidden from him by a veil; and our psycho-analytic training forbids our assuming that these words can have been without significance or have been chosen at haphazard. The veil was torn, strange to say, in one situation only; and that was at the moment when, as a result of an enema, he passed a motion through his anus. He then felt well again, and for a very short while he saw the world clearly. The interpretation of this 'veil' progressed with as much difficulty as we met with in clearing up his fear of the butterfly. Nor did he keep to the veil. It became still more elusive, as a feeling of twilight, '*ténèbres*', and of other impalpable things,

It was not until just before taking leave of the treatment that he remembered having been told that he was born with a caul. He had for that reason always looked on himself as a special child of fortune whom no ill could befall. He did not lose that conviction until he was forced to realize that his gonorrhoeal infection constituted a serious injury to his body. The blow to his narcissism was too much for him and he went to pieces. It may be said that in so doing he was repeating a mechanism that he had already brought into play once before. For his wolf phobia had broken out when he found himself faced by the fact that such a thing as castration was possible; and he clearly classed his gonorrhoea as castration.

Thus the caul was the veil which hid him from the world and hid the world from him. The complaint that he made was in reality a fulfilled wishful phantasy: it exhibited him as back once more in the womb, and was, in fact, a wishful phantasy of flight from the world. It can be translated as follows: 'Life makes me so unhappy! I must get back into the womb!'

But what can have been the meaning of the fact that this veil, which was now symbolic but had once been real, was torn at the moment at which he evacuated his bowels after an enema, and that under this condition his illness left him? The context enables us to reply. If this birth-veil was torn, then he saw the world and was re-born. The stool was the child, as which he was born a second time, to a happier life. Here, then, we have the phantasy of re-birth, to which Jung has recently drawn attention and to which he has assigned such a dominating position in the imaginative life of neurotics.

This would be all very well, if it were the whole story. But certain details of the situation, and a due regard for the connection between it and this particular patient's life-history, compel us to pursue the interpretation further. The necessary condition of his re-birth was that he should have an enema administered to him by a man. (It was not until later on that he was driven by necessity to take this man's place himself.) This can, only have meant that he had identified himself with his mother, that the man was acting as his father, and that the enema was repeating the act of copulation, as the fruit of which the excrement-baby (which was once again himself) would be born. The phantasy of re-birth was therefore bound up closely with the necessary condition of sexual satisfaction from a man. So that the translation now runs to this effect: only on condition that he took the woman's place and substituted himself for his mother, and thus let himself be sexually satisfied by his father and bore him a child - only on that condition would his illness leave him. Here, therefore, the phantasy of re-birth was simply a mutilated and censored version of the homosexual wishful phantasy.

If we look into the matter more closely we cannot help remarking that in this condition which he laid down for his recovery the patient was simply repeating the state of affairs at the time of the 'primal scene'. At that moment he had wanted to substitute himself for his mother; and, as we assumed long ago, it was he himself who, in the scene in question, had produced the excrement-baby. He still remained fixated, as though by a spell, to the scene which had such a decisive effect on his sexual life, and the return of which during the night of the dream brought the onset of his illness. The tearing of the veil was analogous to the opening of his eyes and to the opening of the window. The primal scene had become transformed into the necessary condition for his recovery.

It is easy to make a unified statement of what was expressed on the one hand by the complaint he made and on the other hand by the single exceptional condition under which the complaint no longer held good, and thus to make clear the whole meaning that underlay the two factors: he wished he could be back in the womb, not simply in order that he might then be re-born, but in order that he might be copulated with there by his father, might obtain sexual satisfaction from him, and might bear him a child.

The wish to be born of his father (as he had at first believed was the case), the wish to be sexually satisfied by him, the wish to present him with a child - and all of this at the price of his own masculinity, and expressed in the language of anal erotism - these wishes complete the circle of his fixation upon his father. In them homosexuality has found its furthest and most intimate expression.¹

This instance, I think, throws light on the meaning and origin of the womb-phantasy as well as that of re-birth. The former, the womb-phantasy, is frequently derived (as it was in the present case) from an attachment to the father. There is a wish to be inside the mother's womb in order to replace her during intercourse - in order to take her place in regard to the father. The phantasy of re-birth, on the other hand, is in all probability regularly a softened substitute (a euphemism, one might say) for the phantasy of incestuous intercourse with the mother; to make use of Silberer's expression, it is an *anagogic* abbreviation of it. There is a wish to be back in a situation in which one was in the mother's genitals; and in this connection the man is identifying himself with his own penis and is using it to represent himself. Thus the two phantasies are revealed as each other's counterparts: they give expression, according as the subject's attitude is feminine or masculine, to his wish for sexual intercourse with his father or with his mother. We cannot dismiss the possibility that in the complaint made by our present patient and in the necessary condition laid down for his recovery the two phantasies, that is to say the two incestuous wishes, were united.

¹ A possible subsidiary explanation, namely that the veil represented the hymen which is torn at the moment of intercourse with a man, does not harmonize completely with the necessary condition for his recovery. Moreover it has no bearing on the life of the patient, for whom virginity carried no significance.

I will make a final attempt at re-interpreting the last findings of this analysis in accordance with the scheme of my opponents. The patient lamented his flight from the world in a typical womb-phantasy and viewed his recovery as a typically conceived re-birth. In accordance with the predominant side of his disposition, he expressed the latter in anal symptoms. He next concocted, on the model of his anal phantasy of re-birth, a childhood scene which repeated his wishes in an archaic symbolic medium of expression. His symptoms were then strung together as though they had been derived from a primal scene of that kind. He was driven to embark on this long backward course either because he had come up against some task in life which he was too lazy to perform, or because he had every reason to be aware of his own inferiority and thought he could best protect himself from being slighted by elaborating such contrivances as these.

All this would be very nice, if only the unlucky wretch had not had a dream when he was no more than four years old, which signalized the beginning of his neurosis, which was instigated by his grandfather's story of the tailor and the wolf, and the interpretation of which necessitates the assumption of this primal scene. All the alleviations which the theories of Jung and Adler seek to afford us come to grief, alas, upon such paltry but unimpeachable facts as these. As things stand, it seems to me more probable that the phantasy of re-birth was a derivative of the primal scene than that, conversely, the primal scene was a reflection of the phantasy of re-birth. And we may perhaps suppose, too, that the patient, at a time only four years after his birth, may after all have been too young to be already wishing to be born again. But no, I must take this last argument back; for my own observations show that we have rated the powers of children too low and that there is no knowing what they cannot be given credit for.¹

¹ I admit that this is the most delicate question in the whole domain of psycho-analysis. I did not require the contributions of Adler or Jung to induce me to consider the matter with a critical eye, and to bear in mind the possibility that what analysis puts forward as being forgotten experiences of childhood (and of an improbably early childhood) may on the contrary be based upon phantasies created on occasions occurring late in life. According to this view, wherever we seemed in analyses to see traces of the after-effects of an infantile impression of the kind in question, we should rather have to assume that we were faced by the manifestation of some constitutional factor or of some disposition that had been phylogenetically maintained. On the contrary, no doubt has troubled me more; no other uncertainty has been more decisive in holding me back from publishing my conclusions. I was the first - a point to which none of my opponents have referred - to recognize both the part played by phantasies in symptom-formation and also the 'retrospective phantasying' of late impressions into childhood and their sexualization after the event. (See my *Interpretation of Dreams* (1900a), First Edition, p. 559, and 'Notes upon a Case of Obsessional Neurosis', (1909d).) If, in spite of this, I have held to the more difficult and more improbable view, it has been as a result of arguments such as are forced upon the investigator by the case described in these pages or by any other infantile neurosis - arguments which I once again lay before my readers for their decision.

IX

RECAPITULATIONS AND PROBLEMS

I do not know if the reader of this report of an analysis will have succeeded in forming a clear picture of the origin and development of the patient's illness. I fear that, on the contrary, this will not have been the case. But though on other occasions I have said very little on behalf of my powers in the art of exposition, I should like in the present instance to plead mitigating circumstances. The description of such early phases and of such deep strata of mental life has been a task which has never before been attacked; and it is better to perform that task badly than to take flight before it - a proceeding which would moreover (or so we are told) involve the coward in risks of a certain kind. I prefer, therefore, to put a bold face on it and show that I have not allowed myself to be held back by a sense of my own inferiority.

The case itself was not a particularly favourable one. The advantage of having a wealth of information about the patient's childhood (an advantage which was made possible by the fact that the child could be studied through the medium of the adult) had to be purchased at the expense of the analysis being most terribly disjointed and of the exposition showing corresponding gaps. Personal peculiarities in the patient and a national character that was foreign to ours made the task of feeling one's way into his mind a laborious one. The contrast between the patient's agreeable and affable personality, his acute intelligence and his nice-mindedness on the one hand, and his completely unbridled instinctual life on the other, necessitated an excessively long process of preparatory education, and this made a general perspective more difficult. But the patient himself has no responsibility for that feature of the case which put the severest obstacles in the way of any description of it. In the psychology of adults we have fortunately reached the point of being able to divide mental processes into conscious and unconscious and of being able to give a clearly-worded description of both. With children this distinction leaves us almost completely in the lurch. It is often embarrassing to decide what one would choose to call conscious and what unconscious. Processes which have become the dominant ones, and which from their subsequent behaviour must be equated with conscious ones, have nevertheless not been conscious in the child. It is easy to understand why. In children the conscious has not yet acquired all its characteristics; it is still in process of development, and it does not as yet fully possess the capacity for transposing itself into verbal images. We are constantly guilty of making a confusion between the phenomenon of emergence as a perception in consciousness and the fact of belonging to a hypothetical psychical system to which we ought to assign some conventional name, but which we in fact also call 'consciousness' (the system Cs.). This confusion does no harm when we are giving a psychological description of an adult, but it is misleading when we are dealing with that of a young child. Nor should we be much assisted here if we introduced the 'preconscious'; for a child's preconscious may, in just the same way, fail to coincide with an adult's. We must be content, therefore, with having clearly recognized the obscurity.

It is obvious that a case such as that which is described in these pages might be made an excuse for dragging into the discussion every one of the findings and problems of psycho-analysis. But this would be an endless and unjustifiable labour. It must be recognized that everything cannot be learnt from a single case and that everything cannot be decided by it; we must content ourselves with exploiting whatever it may happen to show most clearly. There are in any case narrow limits to what a psycho-analysis is called upon to explain. For, while it is its business to explain the striking symptoms by revealing their genesis, it is not its business to explain but merely to describe the psychical mechanisms and instinctual processes to which one is led by that means. In order to derive fresh generalizations from what has thus been established with regard to the mechanisms and instincts, it would be essential to have at one's disposal numerous cases as thoroughly and deeply analysed as the present one. But they are not easily to be had, and each one of them requires years of labour. So that advances in these spheres of knowledge must necessarily be slow. There is no doubt a great temptation to content oneself with 'scratching' the mental surface of a number of people and of replacing what is left undone by speculation - the latter being put under the patronage of some school or other of philosophy. Practical requirements may also be adduced in favour of this procedure; but no substitute can satisfy the requirements of science.

I shall now attempt to sketch out a synthetic survey of my patient's sexual development, beginning from its earliest indications. The first that we hear of it is in the disturbance of his appetite; for, taking other observations into account, I am inclined, though with due reservations, to regard that as a result of some process in the sphere of sexuality. I have been driven to regard as the earliest recognizable sexual organization the so-called 'cannibalistic' or 'oral' phase, during which the original attachment of sexual excitation to the nutritional instinct still dominates the scene. It is not to be expected that we should come upon direct manifestations of this phase, but only upon indications of it where disturbances have been set up. Impairment of the nutritional instinct (though this can of course have other causes) draws our attention to a failure on the part of the organism to master its sexual excitation. In this phase the sexual aim could only be cannibalism - devouring; it makes its appearance with our present patient through regression from a higher stage, in the form of fear of 'being eaten by the wolf'. We were, indeed, obliged to translate this into a fear of being copulated with by his father. It is well known that there is a neurosis in girls which occurs at a much later age, at the time of puberty or soon afterwards, and which expresses aversion to sexuality by means of anorexia. This neurosis will have to be brought into relation with the oral phase of sexual life. The erotic aim of the oral organization further makes its appearance at the height of a lover's paroxysm (in such phrases as 'I could eat you up with love') and in affectionate relations with children, when the grown-up person is pretending to be a child himself. I have elsewhere given voice to a suspicion that the father of our present patient used himself to indulge in 'affectionate abuse', and may have played at wolf or dog with the little boy and have threatened as a joke to gobble him up (p. 3524). The patient confirmed this suspicion by his curious behaviour in the transference. Whenever he shrank back on to the transference from the difficulties of the treatment, he used to threaten me with eating me up and later with all kinds of other ill-treatment - all of which was merely an expression of affection.

Permanent marks have been left by this oral phase of sexuality upon the usages of language. People commonly speak for instance, of an 'appetizing' love-object, and describe persons they are fond of as 'sweet'. It will be remembered, too, that our little patient would only eat sweet things. In dreams sweet things and sweetmeats stand regularly for caresses or sexual gratifications.

It appears, moreover, that there is an anxiety belonging to this phase (only, of course, where some disturbance has arisen) which manifests itself as a fear of death and may be attached to anything that is pointed out to the child as being suitable for the purpose. With our patient it was employed to induce him to overcome his loss of appetite and indeed to overcompensate for it. A possible origin of this disturbance of his appetite will be found, if we bear in mind (basing ourselves on the hypothesis that we have so often discussed) that his observation of copulation at the age of one and a half, which produced so many deferred effects, certainly occurred before the time of these difficulties in his eating. So we may perhaps suppose that it accelerated the processes of sexual maturing and consequently did in fact also produce *immediate* effects, though these were insignificant in appearance.

I am of course aware that it is possible to explain the symptoms of this period (the wolf anxiety and the disturbance of appetite) in another and simpler manner, without any reference to sexuality or to a pregenital stage of its organization. Those who like to neglect the indications of neurosis and the interconnections between events will prefer this other explanation, and I shall not be able to prevent their doing so. It is hard to discover any cogent evidence in regard to these beginnings of sexual life except by such roundabout paths as I have indicated.

In the scene with Grusha (at the age of two and a half) we see the little boy at the beginning of a development which, except perhaps for its prematureness, deserves to be considered normal; thus we find

From The History Of An Infantile Neurosis

in it identification with his father, and urethral erotism representing masculinity. It was also completely under the sway of the primal scene. We have hitherto regarded his identification with his father as being narcissistic; but if we take the content of the primal scene into account we cannot deny that it had already reached the stage of genital organization. His male genital organ had begun to play its part and it continued to do so under the influence of his seduction by his sister.

But his seduction gives the impression not merely of having encouraged his sexual development but of having, to an even greater extent, disturbed and diverted it. It offered him a passive sexual aim, which was ultimately incompatible with the action of his male genital organ. At the first external obstacle, the threat of castration from his Nanya, his genital organization, half-hearted as it still was, broke down (at the age of three and a half) and regressed to the stage which had preceded it, namely to that of the sadistic-anal organization, which he might otherwise have passed through, perhaps, with as slight indications as other children.

The sadistic-anal organization can easily be regarded as a continuation and development of the oral one. The violent muscular activity, directed upon the object, by which it is characterized, is to be explained as an action preparatory to eating. The eating then ceases to be a sexual aim, and the preparatory action becomes a sufficient aim in itself. The essential novelty, as compared with the previous stage, is that the receptive passive function becomes disengaged from the oral zone and attached to the anal zone. In this connection we can hardly fail to think of biological parallels or of the theory that the pregenital organizations in man should be regarded as vestiges of conditions which have been permanently retained in several classes of animals. The building up of the instinct for research out of its various components is another characteristic feature of this stage of development.

The boy's anal erotism was not particularly noticeable. Under the influence of his sadism the affectionate significance of faeces gave place to an aggressive one. A part was played in the transformation of his sadism into masochism by a sense of guilt, the presence of which points to developmental processes in spheres other than the sexual one.

His seduction continued to make its influence felt, by maintaining the passivity of his sexual aim. It transformed his sadism to a great extent into the masochism which was its passive counterpart. But it is questionable whether the seduction can be made entirely responsible for this characteristic of passivity, for the child's reaction to his observation of intercourse at the age of one and a half was already preponderantly a passive one. His sympathetic sexual excitement expressed itself by his passing a stool, though it is true that in this behaviour an active element is also to be distinguished. Side by side with the masochism which dominated his sexual impulsions and also found expression in phantasies, his sadism, too, persisted and was directed against small animals. His sexual researches had set in from the time of the seduction and had been concerned, in essence, with two problems: the origin of children and the possibility of losing the genitals. These researches wove themselves into the manifestations of his instinctual impulses, and directed his sadistic propensities on to small animals as being representatives of small children.

We have now carried our account down to about the time of the boy's fourth birthday, and it was at that point that the dream brought into deferred operation his observation of intercourse at the age of one and a half. It is not possible for us completely to grasp or adequately to describe what now ensued. The activation of the picture, which, thanks to the advance in his intellectual development, he was now able to understand, operated not only like a fresh event, but like a new trauma, like an interference from outside analogous to the seduction. The genital organization which had been broken off was re-established at a single blow; but the advance that was achieved in the dream could not be maintained. On the contrary, there came about, by means of a process that can only be equated with a repression, a repudiation of the new element and its replacement by a phobia.

Thus the sadistic-anal organization continued to exist during the phase of the animal phobia which now set in, only it suffered an admixture of anxiety-phenomena. The child persisted in his sadistic as well as in his masochistic activities, but he reacted with anxiety to a portion of them; the conversion of his sadism into its opposite probably made further progress.

The analysis of the anxiety-dream shows us that the repression was connected with his recognition of the existence of castration. The new element was rejected because its acceptance would have cost him his penis. Closer consideration leads us to some such conclusion as the following. What was repressed was the homosexual attitude understood in the genital sense, an attitude which had been formed under the influence of this recognition of castration. But that attitude was retained as regards the unconscious and set up as a dissociated and deeper stratum. The motive force of the repression seems to have been the narcissistic masculinity which attached to the boy's genitals, and which had come into a long-prepared conflict with the passivity of his homosexual sexual aim. The repression was thus a result of his masculinity.

One might be tempted at this point to introduce a slight alteration into psycho-analytic theory. It would seem palpably obvious that the repression and the formation of the neurosis must have originated out of the conflict between masculine and feminine tendencies, that is out of bisexuality. This view of the situation, however is incomplete. Of the two conflicting sexual impulses one was ego-syntonic, while the other offended the boy's narcissistic interest; it was on *that* account that the latter underwent repression. So that in this case, too, it was the ego that put the repression into operation, for the benefit of one of the sexual tendencies. In other cases there is no such conflict between masculinity and femininity; there is only a single sexual tendency present, which seeks for acceptance, but offends against certain forces of the ego and is consequently repelled. Indeed, conflicts between sexuality and the *moral* ego trends are far more common than such as take place within the sphere of sexuality; but a moral conflict of this kind is lacking in our present case. To insist that bisexuality is the motive force leading to repression is to take too narrow a view; whereas if we assert the same of the conflict between the ego and the sexual tendencies (that is, the libido) we shall have covered all possible cases.

The theory of the 'masculine protest', as it has been developed by Adler, is faced by the difficulty that repression by no means always takes the side of masculinity against femininity; there are quite large classes of cases in which it is masculinity that has to submit to repression by the ego.

Moreover, a juster appreciation of the process of repression in our present case would lead us to deny that narcissistic masculinity was the sole motive force. The homosexual attitude which came into being during the dream was of such overwhelming intensity that the little boy's ego found itself unable to cope with it and so defended itself against it by the process of repression. The narcissistic masculinity which attached to his genitals, being opposed to the homosexual attitude, was drawn in, in order to assist the ego in carrying out the task. Merely to avoid misunderstandings, I will add that all narcissistic impulses operate from the ego and have their permanent seat in the ego, and that repressions are directed against libidinal object cathexes.

Let us now leave the process of repression, though we have perhaps not succeeded in dealing with it exhaustively, and let us turn to the boy's state when he awoke from the dream. If it had really been his masculinity that had triumphed over his homosexuality (or femininity) during the dream-process, then we should necessarily find that the dominant trend was an active sexual trend of a character already explicitly masculine. But there is no question of this having happened. The essentials of the sexual organization had not been changed; the sadistic-anal phase persisted, and remained the dominant one. The triumph of his masculinity was shown only in this: that thenceforward he reacted with anxiety to the passive sexual aims of the dominant organization - aims which were masochistic but not feminine. We are not confronted by a triumphant masculine sexual trend, but only by a passive one and a struggle against it.

I can well imagine the difficulties that the reader must find in the sharp distinction (unfamiliar but essential) which I have drawn between 'active' and 'masculine' and between 'passive' and 'feminine'. I shall therefore not hesitate to repeat myself. The state of affairs, then, after the dream, may be described as follows. The sexual trends had been split up; in the unconscious the stage of the genital organization had been reached, and a very intense homosexuality set up; on the top of this (virtually in the conscious) there persisted the earlier sadistic and predominantly masochistic sexual current; the ego had on the whole changed its attitude towards sexuality, for it now repudiated sexuality and rejected the dominant masochistic aims with anxiety, just as it had reacted to the deeper homosexual aims with the formation of a phobia. Thus the result of the dream was not so much the triumph of a masculine current, as a reaction against a feminine and passive one. It would be very forced to ascribe the quality of masculinity to this reaction. The truth is that the ego has no sexual currents, but only an interest in its own self-protection and in the preservation of its narcissism.

Let us now consider the phobia. It came into existence on the level of the genital organization, and shows us the relatively simple mechanism of an anxiety-hysteria. The ego, by developing anxiety, was protecting itself against what it regarded as an overwhelming danger, namely, homosexual satisfaction. But the process of repression left behind it a trace which cannot be overlooked. The object to which the dangerous sexual aim had been attached had to have its place taken in consciousness by another one. What became conscious was fear not of the *father* but of the *wolf*. Nor did the process stop at the formation of a phobia with a single content. A considerable time afterwards the wolf was replaced by the lion. Simultaneously with sadistic impulses against small animals there was a phobia directed towards them, in their capacity of representatives of the boy's rivals, the possible small children. The origin of the butterfly phobia is of especial interest. It was like a repetition of the mechanism that produced the wolf phobia in the dream. Owing to a chance stimulus an old experience, the scene with Grusha, was activated; her threat of castration thus produced deferred effects, though at the time it was uttered it had made no impression.¹

¹ The Grusha scene was, as I have said, a spontaneous product of the patient's memory, and no construction or stimulation by the physician played any part in evoking it. The gaps in it were filled up by the analysis in a fashion which must be regarded as unexceptionable, if any value at all is attached to the analytic method of work. The only possible rationalistic explanation of the phobia would be the following. There is nothing extraordinary, it might be said, in a child that was inclined to be nervous having had an anxiety attack in connection with a yellow-striped butterfly, probably as a result of some inherited tendency to anxiety. (See Stanley Hall, 'A Synthetic Genetic Study of Fear', 1914.) In ignorance of the true causation of his fear, this explanation would proceed, the patient looked about for something in his childhood to which he could connect it; he made use of the chance similarity of names and the recurrence of the stripes as a ground for the construction of an imaginary adventure with the nursery-maid whom he still remembered. When, however, we observe that the trivial details of this went (which, according to this view, was in itself an innocent one) - the scrubbing, the pail and the broom - had enough power over the patient's later life to determine his object-choice permanently and compulsively, then the butterfly phobia seems to have acquired an inexplicable importance. The state of things on this hypothesis is thus seen to be at least as remarkable as on mine, and any advantage that might be claimed for a rationalistic reading of the scene has melted away. The Grusha scene is of particular value to us, since in relation to it we can prepare our judgement upon the less certain primal scene.

It may truly be said that the anxiety that was concerned in the formation of these phobias was a fear of castration. This statement involves no contradiction of the view that the anxiety originated from the repression of homosexual libido. Both modes of expression refer to the same process: namely, the withdrawal of libido by the ego from the homosexual wishful impulse, the libido having then become converted into free anxiety and subsequently bound in phobias. The first method of statement merely mentions in addition the motive by which the ego was actuated.

If we look into the matter more closely we shall see that our patient's first illness (leaving the disturbance of appetite out of account) is not exhausted when we have extracted the phobia from it. It must be regarded as a true hysteria showing not merely anxiety-symptoms but also phenomena of conversion. A portion of the homosexual impulse was retained by the organ concerned in it; from that time forward, and equally during his adult life, his bowel behaved like a hysterically affected organ. The unconscious repressed homosexuality withdrew into his bowel. It was precisely this trait of hysteria which was of such great service in helping to clear up his later illness.

We must now summon up our courage to attack the still more complicated structure of the obsessional neurosis. Let us once more bear the situation in mind: a dominant masochistic sexual current and a repressed homosexual one, and an ego deep in hysterical repudiation of them. What processes transformed this condition into one of obsessional neurosis?

The transformation did not occur spontaneously, through internal development, but through an outside influence. Its visible effect was that the patient's relation to his father, which stood in the foreground, and which had so far found expression in the wolf phobia, was now manifested in obsessional piety. I cannot refrain from pointing out that the course of events in this part of the patient's history affords an unmistakable confirmation of an assertion which I made in *Totem and Taboo* upon the relation of the totem animal to the deity.¹ I there decided in favour of the view that the idea of God was not a development from the totem, but replaced it after arising independently from a root common to both ideas. The totem, I maintained, was the first father-surrogate, and the god was a later one, in which the father had regained his human shape. And we find the same thing with our patient. In his wolf phobia he had gone through the stage of the totemic father-surrogate; but that stage was now broken off, and, as a result of new relations between him and his father, was replaced by a phase of religious piety.

The influence that provoked this transformation was the acquaintance which he obtained through his mother's agency with the doctrines of religion and with the Bible story. This educational measure had the desired effect. The sadistic-masochistic sexual organization came slowly to an end, the wolf phobia quickly vanished, and, instead of sexuality being repudiated with anxiety, a higher method of suppressing it made its appearance. Piety became the dominant force in the child's life. These victories, however, were not won without struggles, of which his blasphemous thoughts were an indication, and of which the establishment of an obsessive exaggeration of religious ceremonial was the result.

Apart from these pathological phenomena, it may be said that in the present case religion achieved all the aims for the sake of which it is included in the education of the individual. It put a restraint on his sexual impulses by affording them a sublimation and a safe mooring; it lowered the importance of his family relationships, and thus protected him from the threat of isolation by giving him access to the great community of mankind. The untamed and fear-ridden child became social, well-behaved, and amenable to education.

¹ *Totem and Taboo* (1912-13), p. 2788.

The chief motive force of the influence which religion had on him was his identification with the figure of Christ, which came particularly easily to him owing to the accident of the date of his birth. Along this path his extravagant love of his father, which had made the repression necessary, found its way at length to an ideal sublimation. As Christ, he could love his father, who was now called God, with a fervour which had sought in vain to discharge itself so long as his father had been a mortal. The means by which he could bear witness to this love were laid down by religion, and they were not haunted by that sense of guilt from which his individual feelings of love could not set themselves free. In this way it was still possible for him to drain off his deepest sexual current, which had already been precipitated in the form of unconscious homosexuality; and at the same time his more superficial masochistic impulsion found an incomparable sublimation, without much renunciation, in the story of the Passion of Christ, who, at the behest of his divine Father and in his honour, had let himself be ill-treated and sacrificed. So it was that religion did its work for the hard pressed child - by the combination which it afforded the believer of satisfaction, of sublimation, of diversion from sensual processes to purely spiritual ones, and of access to social relationships.

The opposition which he at first offered to religion had three different points of origin. To begin with, there was, in general, his characteristic (which we have seen exemplified already) of fending off all novelties. Any position of the libido which he had once taken up was obstinately defended by him from fear of what he would lose by giving it up and from distrust of the probability of a complete substitute being afforded by the new position that was in view. This is an important and fundamental psychological peculiarity, which I described in my *Three Essays on the Theory of Sexuality* (1905d) as a susceptibility to 'fixation'. Under the name of psychical 'inertia' Jung has attempted to erect it into the principal cause of all the failures of neurotics. I think he is wrong in this; for this factor has a far more general application and plays an important part in the lives of the non-neurotic as well. Great mobility or sluggishness of libidinal cathexes (as well as of other kinds of energetic cathexes) are special characteristics which attach to many normal people and by no means to all neurotics, and which have hitherto not been brought into relation with other qualities. They are, as it were, like prime numbers, not further divisible. We only know one thing about them, and that is that mobility of the mental cathexes is a quality which shows striking diminution with the advance of age. This has given us one of the indications of the limits within which psycho-analytic treatment is effective. There are some people, however, who retain this mental plasticity far beyond the usual age-limit, and others who lose it very prematurely. If the latter are neurotics, we make the unwelcome discovery that it is impossible to undo developments in them which, in apparently similar circumstances, have been easily dealt with in other people. So that in considering the conversion of psychical energy no less than of physical, we must make use of the concept of an *entropy*, which opposes the undoing of what has already occurred.

A second point of attack was afforded by the circumstance that religious doctrine is itself based upon a by no means unambiguous relation to God the Father, and in fact bears the stamp of the ambivalent attitude which presided over its origin. The patient's own ambivalence, which he possessed in a high degree of development, helped him to detect the same feature in religion, and he brought to bear on that feature those acute powers of criticism whose presence could not fail to astonish us in a child of four and a half.

But there was a third factor at work, which was certainly the most important of all, and to the operation of which we must ascribe the pathological products of his struggle against religion. The truth was that the mental current which impelled him to turn to men as sexual objects and which should have been sublimated by religion was no longer free; a portion of it was cut off by repression and so withdrawn from the possibility of sublimation and tied to its original sexual aim. In virtue of this state of things, the repressed portion kept making efforts to forge its way through to the sublimated portion or to drag down the latter to itself. The first ruminations which he wove round the figure of Christ already involved the question whether that sublime son could also fulfil the sexual relationship to his father which the patient had retained in his unconscious. The only result of his repudiation of these efforts was the production of apparently blasphemous obsessive thoughts, in which his physical affection for God asserted itself in the form of a debasement. A violent defensive struggle against these compromises then inevitably led to an obsessive exaggeration of all the activities which are prescribed for giving expression to piety and a pure love of God. Religion won in the end, but its instinctual foundations proved themselves to be incomparably stronger than the durability of the products of their sublimation. As soon as the course of events presented him with a new father-surrogate, who threw his weight into the scale against religion, it was dropped and replaced by something else. Let us further bear in mind, as an interesting complication, that his piety originated under the influence of women (his mother and his nurse), while it was a masculine influence that set him free from it.

The origin of this obsessional neurosis on the basis of the sadistic-anal organization confirms on the whole what I have said elsewhere on the predisposition to obsessional neurosis (1913ⁱ). The previous existence, however, of a severe hysteria in the present case makes it more obscure in this respect.

I will conclude my survey of the patient's sexual development by giving some brief glimpses of its later vicissitudes. During the years of puberty a markedly sensual, masculine current, with a sexual aim suitable to the genital organization, made its appearance in him; it must be regarded as normal, and its history occupied the period up to the time of his later illness. It was connected directly with the Grusha scene, from which it borrowed its characteristic feature - a compulsive falling in love that came on and passed off by sudden fits. This current had to struggle against the inhibitions that were derived from his infantile neurosis. There had been a violent revulsion in the direction of women, and he had thus won his way to complete masculinity. From that time forward he retained women as his sexual object; but he did not enjoy this possession, for a powerful, and now entirely unconscious, inclination towards men, in which were united all the forces of the earlier phases of his development, was constantly drawing him away from his female objects and compelling him in the intervals to exaggerate his dependence upon women. He kept complaining during the treatment that he could not bear having to do with women, and all our labours were directed towards disclosing to him his unconscious relation to men. The whole situation might be summarized in the shape of a formula. His childhood had been marked by a wavering between activity and passivity, his puberty by a struggle for masculinity, and the period after he had fallen ill by a fight for the object of his masculine desires. The precipitating cause of his neurosis was not one of the types of onset which I have been able to put together as special cases of 'frustration',¹ and it thus draws attention to a gap in that classification. He broke down after an organic affection of the genitals had revived his fear of castration, shattered his narcissism, and compelled him to abandon his hope of being personally favoured by destiny. He fell ill, therefore, as the result of a *narcissistic* 'frustration'. This excessive strength of his narcissism was in complete harmony with the other indications of an inhibited sexual development: with the fact that so few of his psychical trends were concentrated in his heterosexual object choice, in spite of all its energy, and that his homosexual attitude, standing so much nearer to narcissism, persisted in him as an unconscious force with such very great tenacity. Naturally, where disturbances like these are present, psycho-analytic treatment cannot bring about any instantaneous revolution or put matters upon a level with a normal development: it can only get rid of the obstacles and clear the path, so that the influences of life may be able to further development along better lines.

¹ 'Types of Onset of Neurosis' (1912c).

I shall now bring together some peculiarities of the patient's mentality which were revealed by the psycho-analytic treatment but were not further elucidated and were accordingly not susceptible to direct influence. Such were his tenacity of fixation, which has already been discussed, his extraordinary propensity to ambivalence, and (as a third trait in a constitution which deserves the name of archaic) his power of maintaining simultaneously the most various and contradictory libidinal cathexes, all of them capable of functioning side by side. His constant wavering between these (a characteristic which for a long time seemed to block the way to recovery and progress in the treatment) dominated the clinical picture during his adult illness, which I have scarcely been able to touch upon in these pages. This was undoubtedly a trait belonging to the general character of the unconscious, which in his case had persisted into processes that had become conscious. But it showed itself only in the products of affective impulses; in the region of pure logic he betrayed, on the contrary, a peculiar skill in unearthing contradictions and inconsistencies. So it was that his mental life impressed one in much the same way as the religion of Ancient Egypt, which is so unintelligible to us because it preserves the earlier stages of its development side by side with the end-products, retains the most ancient gods and their attributes along with the most modern ones, and thus, as it were, spreads out upon a two-dimensional surface what other instances of evolution show us in the solid.

I have now come to the end of what I had to say about this case. There remain two problems, of the many that it raises, which seem to me to deserve special emphasis. The first relates to the phylogenetically inherited schemata, which, like the categories of philosophy, are concerned with the business of 'placing' the impressions derived from actual experience. I am inclined to take the view that they are precipitates from the history of human civilization. The Oedipus complex, which comprises a child's relation to his parents, is one of them - is, in fact, the best known member of the class. Wherever experiences fail to fit in with the hereditary schema, they become remodelled in the imagination - a process which might very profitably be followed out in detail. It is precisely such cases that are calculated to convince us of the independent existence of the schema. We are often able to see the schema triumphing over the experience of the individual; as when in our present case the boy's father became the castrator and the menace of his infantile sexuality in spite of what was in other respects an inverted Oedipus complex. A similar process is at work where a nurse comes to play the mother's part or where the two become fused together. The contradictions between experience and the schema seem to supply the conflicts of childhood with an abundance of material.

The second problem is not far removed from the first, but it is incomparably more important. If one considers the behaviour of the four-year-old child towards the re-activated primal scene,¹ or even if one thinks of the far simpler reactions of the one-and-a-half-year-old child when the scene was actually experienced, it is hard to dismiss the view that some sort of hardly definable knowledge, something, as it were, preparatory to an understanding, was at work in the child at the time.² We can form no conception of what this may have consisted in; we have nothing at our disposal but the single analogy - and it is an excellent one - of the far-reaching *instinctive* knowledge of animals.

If human beings too possessed an instinctive endowment such as this, it would not be surprising that it should be very particularly concerned with the processes of sexual life, even though it could not be by any means confined to them. This instinctive factor would then be the nucleus of the unconscious, a primitive kind of mental activity, which would later be dethroned and overlaid by human reason, when that faculty came to be acquired, but which in some people, perhaps in every one, would retain the power of drawing down to it the higher mental processes. Repression would be the return to this instinctive stage, and man would thus be paying for his great new acquisition with his liability to neurosis, and would be bearing witness by the possibility of the neuroses to the existence of those earlier, instinct-like, preliminary stages. The significance of the traumas of early childhood would lie in their contributing material to this unconscious which would save it from being worn away by the subsequent course of development.

¹ I may disregard the fact that it was not possible to put this behaviour into words until twenty years afterwards; for all the effects that we traced back to the scene had already been manifested in the form of symptoms, obsessions, etc., in the patient's childhood and long before the analysis. It is also a matter of indifference in this connection whether we choose to regard it as a primal *scene* or as a primal *phantasy*.

² I must once more emphasize the fact that these reflections would be vain if the dream and the neurosis had not themselves occurred in infancy.

I am aware that expression has been given in many quarters to thoughts like these, which emphasize the hereditary, phylogenetically acquired factor in mental life. In fact, I am of opinion that people have been far too ready to find room for them and ascribe importance to them in psycho-analysis. I consider that they are only admissible when psycho-analysis strictly observes the correct order of precedence, and, after forcing its way through the strata of what has been acquired by the individual, comes at last upon traces of what has been inherited.¹

¹ (*Footnote added 1923:*) I will once more set out here the chronology of the events mentioned in this case history.
Born on Christmas Day.

1 ½ years old: Malaria. Observation of his parents copulating; or observation of them when they were together, into which he later introduced a phantasy of them copulating.

Just before 2 ½: Scene with Grusha.

2 ½: Screen memory of his parents' departure with his sister. This showed him alone with his Nanya and so disowned Grusha and his sister.

Before 3 ¼: His mother's laments to the doctor.

3 ¼: Beginning of his seduction by his sister. Soon afterwards the threat of castration from his Nanya.

3 ½: The English governess. Beginning of the change in his character.

4: The wolf dream. Origin of the phobia.

4 ½: Influence of the Bible story. Appearance of the obsessional symptoms.

Just before 5: Hallucination of the loss of his finger.

5: Departure from the first estate.

After 6: Visit to his sick father.

8 and 10: Final outbreaks of the obsessional neurosis.

It will have been easy to guess from my account that the patient was a Russian. I parted from him, regarding him as cured, a few weeks before the unexpected outbreak of the Great War; and I did not see him again until the shifting chances of the war had given the Central European Powers access to South Russia. He then came to Vienna and reported that immediately after the end of the treatment he had been seized with a longing to tear himself free from my influence. After a few months' work, a piece of the transference which had not hitherto been overcome was successfully dealt with. Since then the patient has felt normal and has behaved unexceptionably, in spite of the war having robbed him of his home, his possessions, and all his family relationships. It may be that his very misery, by gratifying his sense of guilt, contributed to the consolidation of his recovery.

ON TRANSFORMATIONS OF INSTINCT AS EXEMPLIFIED IN ANAL EROTISM
(1917)

Intentionally left blank

ON TRANSFORMATIONS OF INSTINCT AS EXEMPLIFIED IN ANAL EROTISM

Some years ago, observations made during psycho-analysis led me to suspect that the constant co-existence in any one of the three character-traits of *orderliness*, *parsimony* and *obstinacy* indicated an intensification of the anal-erotic components in his sexual constitution, and that these modes of reaction, which were favoured by his ego, had been established during the course of his development through the assimilation of his anal erotism.¹

In that publication my main object was to make known the fact of this established relation; I was little concerned about its theoretical significance. Since then there has been a general consensus of opinion that each one of the three qualities, avarice, pedantry and obstinacy, springs from anal-erotic sources - or, to express it more cautiously and more completely - draws powerful contributions from those sources. The cases in which these defects of character were combined and which in consequence bore a special stamp (the 'anal character') were merely extreme instances, which were bound to betray the particular connection that interests us here even to an unobservant eye.

As a result of numerous impressions, and in particular of one specially cogent analytical observation, I came to the conclusion a few years later that in the development of the libido in man the phase of genital primacy must be preceded by a 'pregenital organization' in which sadism and anal erotism play the leading parts.²

From that moment we had to face the problem of the later history of the anal-erotic instinctual impulses. What becomes of them when, owing to the establishment of a definitive genital organization, they have lost their importance in sexual life? Do they preserve their original nature, but in a state of repression? Are they sublimated or assimilated by transformation into character-traits? Or do they find a place within the new organization of sexuality characterized by genital primacy? Or, since none of these vicissitudes of anal erotism is likely to be the only one, to what extent and in what way does each of them share in deciding its fate? For the organic sources of anal erotism cannot of course be buried as a result of the emergence of the genital organization.

¹ 'Character and Anal Erotism' (1908*b*).

² 'The Predisposition to Obsessional Neurosis' (1913*j*).

One would think that there could be no lack of material from which to provide an answer, since the processes of development and transformation in question must have taken place in everyone undergoing analysis. Yet the material is so obscure, the abundance of ever-recurring impressions so confusing, that even now I am unable to solve the problem fully and can do no more than make some contributions to its solution. In making them I need not refrain from mentioning, where the context allows it, other instinctual transformations besides anal-erotic ones. Finally, it scarcely requires to be emphasized that the developmental events here described - just as the others found in psycho-analysis - have been inferred from the regressions into which they had been forced by neurotic processes.

As a starting-point for this discussion we may take the fact that it appears as if in the products of the unconscious - spontaneous ideas, phantasies and symptoms - the concepts *faeces* (money, gift), *baby* and *penis* are ill-distinguished from one another and are easily interchangeable. We realize, of course, that to express oneself in this way is incorrectly to apply to the sphere of the unconscious terms which belong properly to other regions of mental life, and that we have been led astray by the advantages offered by an analogy. To put the matter in a form less open to objection, these elements in the unconscious are often treated as if they were equivalent and could replace one another freely.

This is most easily seen in the relation between 'baby' and 'penis'. It cannot be without significance that in the symbolic language of dreams, as well as of everyday life, both may be replaced by the same symbol; both baby and penis are called a 'little one'. It is a well-known fact that symbolic speech often ignores difference of sex. The 'little one', which originally meant the male genital organ, may thus have acquired a secondary application to the female genitals.

If we penetrate deeply enough into the neurosis of a woman, we not infrequently meet with the repressed wish to possess a penis like a man. We call this wish 'envy for a penis' and include it in the castration complex. Chance mishaps in the life of such a woman, mishaps which are themselves frequently the result of a very masculine disposition, have re-activated this infantile wish and, through the backward flow of libido, made it the chief vehicle of her neurotic symptoms. In other women we find no evidence of this wish for a penis; it is replaced by the wish for a baby, the frustration of which in real life can lead to the outbreak of a neurosis. It looks as if such women had understood (although this could not possibly have acted as a motive) that nature has given babies to women as a substitute for the penis that has been denied them. With other women, again, we learn that both wishes were present in their childhood and that one replaced the other. At first they had wanted a penis like a man; then at a later, though still childish, stage there appeared instead the wish for a baby. The impression is forced upon us that this variety in our findings is caused by accidental factors during childhood (e.g. the presence or absence of brothers or the birth of a new baby at some favourable time of life), so that the wish for a penis and the wish for a baby would be fundamentally identical.

We can say what the ultimate outcome of the infantile wish for a penis is in women in whom the determinants of a neurosis in later life are absent: it changes into the wish for a *man*, and thus puts up with the man as an appendage to the penis. This transformation, therefore, turns an impulse which is hostile to the female sexual function into one which is favourable to it. Such women are in this way made capable of an erotic life based on the masculine type of object-love, which can exist alongside the feminine one proper, derived from narcissism. We already know that in other cases it is only a baby that makes the transition from narcissistic self-love to object-love possible. So that in this respect too a baby can be represented by the penis.

I have had occasional opportunities of being told women's dreams that had occurred after their first experience of intercourse. They revealed an unmistakable wish in the woman to keep for herself the penis which she had felt. Apart from their libidinal origin, then, these dreams indicated a temporary regression from man to penis as the object of her wish. One would certainly be inclined to trace back the wish for a man in a purely rationalistic way to the wish for a baby, since a woman is bound to understand sooner or later that there can be no baby without the co-operation of a man. It is, however, more likely that the wish for a man arises independently of the wish for a baby, and that when it arises - from understandable motives belonging entirely to ego-psychology - the original wish for a penis becomes attached to it as an unconscious libidinal reinforcement. The importance of the process described lies in the fact that a part of the young woman's narcissistic masculinity is thus changed into femininity, and so can no longer operate in a way harmful to the female sexual function.

Along another path, a part of the erotism of the pregenital phase, too, becomes available for use in the phase of genital primacy. The baby is regarded as 'lump' (cf. the analysis of 'Little Hans'), as something which becomes detached from the body by passing through the bowel. A certain amount of libidinal cathexis which originally attached to the contents of the bowel can thus be extended to the baby born through it. Linguistic evidence of this identity of baby and faeces is contained in the expression 'to give someone a baby'. For its faeces are the infant's first gift, a part of his body which he will give up only on persuasion by someone he loves, to whom indeed, he will make a spontaneous gift of it as a token of affection; for, as a rule, infants do not dirty strangers. (There are similar if less intense reactions with urine.) Defaecation affords the first occasion on which the child must decide between a narcissistic and an object-loving attitude. He either parts obediently with his faeces, 'sacrifices' them to his love, or else retains them for purposes of auto-erotic satisfaction and later as a means of asserting his own will. If he makes the latter choice we are in the presence of defiance (obstinacy) which, accordingly, springs from a narcissistic clinging to anal erotism.

It is probable that the first meaning which a child's interest in faeces develops is that of 'gift' rather than 'gold' or 'money'. The child knows no money apart from what is given him - no money acquired and none inherited of his own. Since his faeces are his first gift, the child easily transfers his interest from that substance to the new one which he comes across as the most valuable gift in life. Those who question this derivation of gifts should consider their experience of psycho-analytic treatment, study the gifts they receive as doctors from their patients, and watch the storms of transference which a gift from them can rouse in their patients.

Thus the interest in faeces is continued partly as interest in money, partly as a wish for a baby, in which latter an anal-erotic and a genital impulse ('envy for a penis') converge. But the penis has another anal-erotic significance apart from its relation to the interest in a baby. The relationship between the penis and the passage lined with mucous membrane which it fills and excites already has its prototype in the pregenital, anal-sadistic phase. The faecal mass, or as one patient called it, the faecal 'stick', represents as it were the first penis, and the stimulated mucous membrane of the rectum represents that of the vagina. There are people whose anal erotism remains vigorous and unmodified up to the age preceding puberty (ten to twelve years); we learn from them that during the pregenital phase they had already developed in phantasy and in perverse play an organization analogous to the genital one, in which penis and vagina were represented by the faecal stick and the rectum. In other people - obsessional neurotics - we can observe the result of a regressive debasement of the genital organization. This is expressed in the fact that every phantasy originally conceived on the genital level is transposed to the anal level - the penis being replaced by the faecal mass and the vagina by the rectum.

As the interest in faeces recedes in a normal way, the organic analogy we have described here has the effect of transferring the interest on to the penis. When, later, in the course of the child's researches he discovers that babies are born from the bowel, they inherit the greater part of his anal erotism; they have, however, been preceded by the penis in this as well as in another sense.

I feel sure that by this time the manifold interrelations of the series - faeces, penis, baby - have become totally unintelligible; so I will try to remedy the defect by presenting them diagrammatically, and in considering the diagram we can review the same material in a different order. Unfortunately, this technical device is not sufficiently pliable for our purpose, or possibly we have not yet learned to use it with effect. In any case I hope the reader will not expect too much from it.

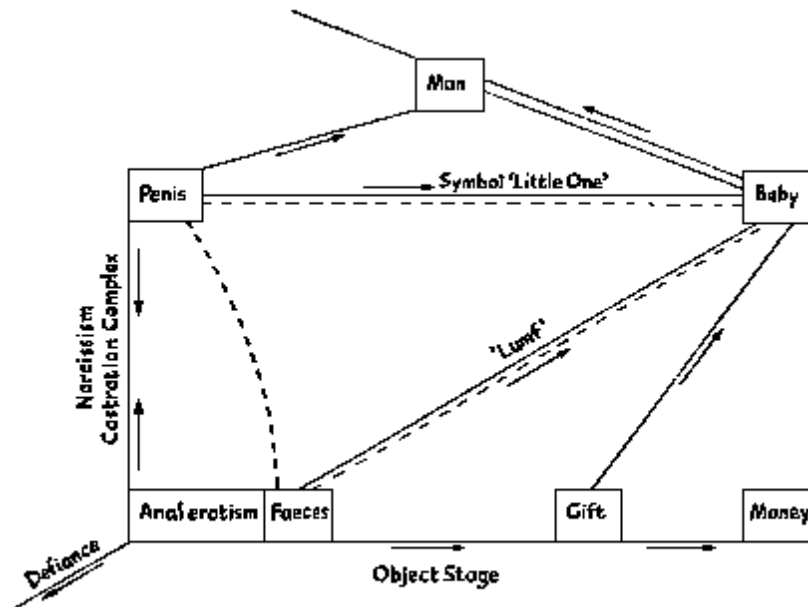

Fig. 2.

Anal eroticism finds a narcissistic application in the production of defiance, which constitutes an important reaction on the part of the ego against demands made by other people. Interest in faeces is carried over first to interest in gifts, and then to interest in money. In girls, the discovery of the penis gives rise to envy for it, which later changes into the wish for a man as the possessor of a penis. Even before this the wish for a penis has changed into the wish for a baby, or the latter wish has taken the place of the former one. An organic analogy between penis and baby (dotted line) is expressed by the existence of a symbol ('little one') common to both. A rational wish (double line) then leads from the wish for a baby to the wish for a man: we have already appreciated the importance of this instinctual transformation.

Another part of the nexus of relations can be observed much more clearly in the male. It arises when the boy's sexual researches lead him to the discovery of the absence of a penis in women. He concludes that the penis must be a detachable part of the body, something analogous to faeces, the first piece of bodily substance the child had to part with. Thus the old anal defiance enters into the composition of the castration complex. The organic analogy which enabled the intestinal contents to be the forerunner of the penis during the pregenital phase cannot come into account as a motive; but the boy's sexual researches lead him to a psychical substitute for it. When a baby appears on the scene he regards it as 'lumpf', in accordance with those researches, and he cathects it with powerful anal-erotic interest. When social experiences teach that a baby is to be regarded as a love-token, a gift, the wish for a baby receives a second contribution from the same source. Faeces, penis and baby are all three solid bodies; they all three, by forcible entry or expulsion, stimulate a membranous passage, i.e. the rectum and the vagina, the latter being as it were 'taken on lease' from the rectum, as Lou Andreas-Salomé aptly remarks.¹ Infantile sexual researches can only lead to the conclusion that the baby follows the same route as the faecal mass. The function of the penis is not usually discovered by those researches. But it is interesting to note that after so many detours an organic correspondence reappears in the psychical sphere as an unconscious identity.

¹ In her paper "'Anal" und "Sexual"' (1916).

A DIFFICULTY IN THE PATH OF PSYCHO-ANALYSIS
(1917)

Intentionally left blank

A DIFFICULTY IN THE PATH OF PSYCHO-ANALYSIS

I will say at once that it is not an intellectual difficulty I am thinking of, not anything that makes psycho-analysis hard for the hearer or reader to understand, but an affective one - something that alienates the feelings of those who come into contact with it, so that they become less inclined to believe in it or take an interest in it. As will be observed, the two kinds of difficulty amount to the same thing in the end. Where sympathy is lacking, understanding will not come very easily.

My present readers, I take it, have not so far had anything to do with the subject and I shall be obliged, therefore, to go back some distance. Out of a great number of individual observations and impressions something in the nature of a theory has at last shaped itself in psycho-analysis, and this is known by the name of the 'libido theory'. As is well known, psycho-analysis is concerned with the elucidation and removal of what are called nervous disorders. A starting-point had to be found from which to approach this problem, and it was decided to look for it in the instinctual life of the mind. Hypotheses about the instincts in man came to form the basis, therefore, of our conception of nervous disease.

Psychology as it is taught academically gives us but very inadequate replies to questions concerning our mental life, but in no direction is its information so meagre as in this matter of the instincts.

It is open to us to make our first soundings as we please. The popular view distinguishes between hunger and love, as being the representatives of the instincts which aim respectively at the preservation of the individual and at the reproduction of the species. We accept this very evident distinction, so that in psycho-analysis too we make a distinction between the self-preservative or ego-instincts on the one hand and the sexual instincts on the other. The force by which the sexual instinct is represented in the mind we call 'libido' - sexual desire - and we regard it as something analogous to hunger, the will to power, and so on, where the ego-instincts are concerned.

With this as a starting-point we go on to make our first important discovery. We learn that, when we try to understand neurotic disorders, by far the greater significance attaches to the sexual instincts; that in fact neuroses are the specific disorders, so to speak, of the sexual function; that in general whether or not a person develops a neurosis depends on the quantity of his libido, and on the possibility of satisfying it and of discharging it through satisfaction; that the form taken by the disease is determined by the way in which the individual passes through the course of development of his sexual function, or, as we put it, by the fixations his libido has undergone in the course of its development; and, further, that by a special, not very simple technique for influencing the mind we are able to throw light on the nature of some groups of neuroses and at the same time to do away with them. Our therapeutic efforts have their greatest success with a certain class of neuroses which proceed from a conflict between the ego-instincts and the sexual instincts. For in human beings it may happen that the demands of the sexual instincts, whose reach of course extends far beyond the individual, seem to the ego to constitute a danger which threatens its self-preservation or its self-esteem. The ego then assumes the defensive, denies the sexual instincts the satisfaction they desire and forces them into those by-paths of substitutive satisfaction which become manifest as nervous symptoms.

The psycho-analytic method of treatment is then able to subject this process of repression to revision and to bring about a better solution of the conflict - one that is compatible with health. Unintelligent opposition accuses us of one-sidedness in our estimate of the sexual instincts. 'Human beings have other interests besides sexual ones,' they say. We have not forgotten or denied this for a moment. Our one-sidedness is like that of the chemist, who traces all compounds back to the force of chemical attraction. He is not on that account denying the force of gravity; he leaves that to the physicist to deal with.

During the work of treatment we have to consider the distribution of the patient's libido; we look for the object presentations to which it is bound and free it from them, so as to place it at the disposal of the ego. In the course of this, we have come to form a very curious picture of the original, primal distribution of libido in human beings. We have been driven to assume that at the beginning of the development of the individual all his libido (all his erotic tendencies, all his capacity for love) is tied to himself - that as we say, it cathects his own ego. It is only later that, being attached to the satisfaction of the major vital needs, the libido flows over from the ego on to external objects. Not till then are we able to recognize the libidinal instincts as such and distinguish them from the ego instincts. It is possible for the libido to become detached from these objects and withdrawn again into the ego.

The condition in which the ego retains the libido is called by us 'narcissism', in reference to the Greek legend of the youth Narcissus who was in love with his own reflection.

Thus in our view the individual advances from narcissism to object-love. But we do not believe that the *whole* of the libido ever passes over from the ego to objects. A certain quantity of libido is always retained in the ego; even when object-love is highly developed, a certain amount of narcissism persists. The ego is a great reservoir from which the libido that is destined for objects flows out and into which it flows back from those objects. Object-libido was at first ego-libido and can be transformed back into ego-libido. For complete health it is essential that the libido should not lose this full mobility. As an illustration of this state of things we may think of an amoeba, whose viscous substance puts out pseudopodia, elongations into which the substance of the body extends but which can be retracted at any time so that the form of the protoplasmic mass is restored.

What I have been trying to describe in this outline is the *libido theory* of the neuroses, upon which are founded all our conceptions of the nature of these morbid states, together with our therapeutic measures for relieving them. We naturally regard the premises of the libido theory as valid for normal behaviour as well. We speak of the narcissism of small children, and it is to the excessive narcissism of primitive man that we ascribe his belief in the omnipotence of his thoughts and his consequent attempts to influence the course of events in the external world by the technique of magic.

After this introduction I propose to describe how the universal narcissism of men, their self-love, has up to the present suffered three severe blows from the researches of science.

(a) In the early stages of his researches, man believed at first that his dwelling-place, the earth, was the stationary centre of the universe, with the sun, moon and planets circling round it. In this he was naïvely following the dictates of his sense perceptions, for he felt no movement of the earth, and wherever he had an unimpeded view he found himself in the centre of a circle that enclosed the external world. The central position of the earth, moreover, was a token to him of the dominating part played by it in the universe and appeared to fit in very well with his inclination to regard himself as lord of the world.

The destruction of this narcissistic illusion is associated in our minds with the name and work of Copernicus in the sixteenth century. But long before his day the Pythagoreans had already cast doubts on the privileged position of the earth, and in the third century B. C. Aristarchus of Samos had declared that the earth was much smaller than the sun and moved round that celestial body. Even the great discovery of Copernicus, therefore, had already been made before him. When this discovery achieved general recognition, the self-love of mankind suffered its first blow, the *cosmological* one.

(b) In the course of the development of civilization man acquired a dominating position over his fellow-creatures in the animal kingdom. Not content with this supremacy, however, he began to place a gulf between his nature and theirs. He denied the possession of reason to them, and to himself he attributed an immortal soul, and made claims to a divine descent which permitted him to break the bond of community between him and the animal kingdom. Curiously enough, this piece of arrogance is still foreign to children, just as it is to primitive and primæval man. It is the result of a later, more pretentious stage of development. At the level of totemism primitive man had no repugnance to tracing his descent from an animal ancestor. In myths, which contain the precipitate of this ancient attitude of mind, the gods take animal shapes, and in the art of earliest times they are portrayed with animals' heads. A child can see no difference between his own nature and that of animals. He is not astonished at animals thinking and talking in fairy-tales; he will transfer an emotion of fear which he feels for his human father onto a dog or a horse, without intending any derogation of his father by it. Not until he is grown up does he become so far estranged from animals as to use their names in vilification of human beings.

We all know that little more than half a century ago the researches of Charles Darwin and his collaborators and forerunners put an end to this presumption on the part of man. Man is not a being different from animals or superior to them; he himself is of animal descent, being more closely related to some species and more distantly to others. The acquisitions he has subsequently made have not succeeded in effacing the evidences, both in his physical structure and in his mental dispositions, of his parity with them. This was the second, the *biological* blow to human narcissism.

(c) The third blow, which is psychological in nature, is probably the most wounding.

Although thus humbled in his external relations, man feels himself to be supreme within his own mind. Somewhere in the core of his ego he has developed an organ of observation to keep a watch on his impulses and actions and see whether they harmonize with its demands. If they do not, they are ruthlessly inhibited and withdrawn. His internal perception, consciousness, gives the ego news of all the important occurrences in the mind's working, and the will, directed by these reports, carries out what the ego orders and modifies anything that seeks to accomplish itself spontaneously. For this mind is not a simple thing; on the contrary, it is a hierarchy of superordinated and subordinated agencies, a labyrinth of impulses striving independently of one another towards action, corresponding with the multiplicity of instincts and of relations with the external world, many of which are antagonistic to one another and incompatible. For proper functioning it is necessary that the highest of these agencies should have knowledge of all that is going forward and that its will should penetrate everywhere, so as to exert its influence. And in fact the ego feels secure both as to the completeness and trustworthiness of the reports it receives and as to the openness of the channels through which it enforces its commands.

In certain diseases - including the very neuroses of which we have made special study - things are different. The ego feels uneasy; it comes up against limits to its power in its own house, the mind. Thoughts emerge suddenly without one's knowing where they come from, nor can one do anything to drive them away. These alien guests even seem to be more powerful than those which are at the ego's command. They resist all the well-proved measures of enforcement used by the will, remain unmoved by logical refutation, and are unaffected by the contradictory assertions of reality. Or else impulses appear which seem like those of a stranger, so that the ego disowns them; yet it has to fear them and take precautions against them. The ego says to itself: 'This is an illness, a foreign invasion.' It increases its vigilance, but cannot understand why it feels so strangely paralysed.

Psychiatry, it is true, denies that such things mean the intrusion into the mind of evil spirits from without; beyond this, however, it can only say with a shrug: 'Degeneracy, hereditary disposition, constitutional inferiority!' Psycho-analysis sets out to explain these uncanny disorders; it engages in careful and laborious investigations, devises hypotheses and scientific constructions, until at length it can speak thus to the ego:-

'Nothing has entered into you from without; a part of the activity of your own mind has been withdrawn from your knowledge and from the command of your will. That, too, is why you are so weak in your defence; you are using one part of your force to fight the other part and you cannot concentrate the whole of your force as you would against an external enemy. And it is not even the worst or least important part of your mental forces that has thus become antagonistic to you and independent of you. The blame, I am bound to say, lies with yourself. You over-estimated your strength when you thought you could treat your sexual instincts as you liked and could utterly ignore their intentions. The result is that they have rebelled and have taken their own obscure paths to escape this suppression; they have established their rights in a manner you cannot approve. How they have achieved this, and the paths which they have taken, have not come to your knowledge. All you have learned is the *outcome* of their work - the symptom which you experience as suffering. Thus you do not recognize it as a derivative of your own rejected instincts and do not know that it is a substitutive satisfaction of them.

'The whole process, however, only becomes possible through the single circumstance that you are mistaken in another important point as well. You feel sure that you are informed of all that goes on in your mind if it is of any importance at all, because in that case, you believe, your consciousness gives you news of it. And if you have had no information of something in your mind you confidently assume that it does not exist there. Indeed, you go so far as to regard what is "mental" as identical with what is "conscious" - that is, with what is known to you in spite of the most obvious evidence that a great deal more must constantly be going on in your mind than can be known to your consciousness. Come, let yourself be taught something on this one point! What is in your mind does not coincide with what you are conscious of; whether something is going on in your mind and whether you hear of it, are two different things. In the ordinary way, I will admit, the intelligence which reaches your consciousness is enough for your needs; and you may cherish the illusion that you learn of all the more important things. But in some cases, as in that of an instinctual conflict such as I have described, your intelligence service breaks down and your will then extends no further than your knowledge. In every case, however, the news that reaches your consciousness is incomplete and often not to be relied on. Often enough, too, it happens that you get news of events only when they are over and when you can no longer do anything to change them. Even if you are not ill, who can tell all that is stirring in your mind of which you know nothing or are falsely informed? You behave like an absolute ruler who is content with the information supplied him by his highest officials and never goes among the people to hear their voice. Turn your eyes inward, look into your own depths, learn first to know yourself! Then you will understand why you were bound to fall ill; and perhaps, you will avoid falling ill in future.'

It is thus that psycho-analysis has sought to educate the ego. But these two discoveries - that the life of our sexual instincts cannot be wholly tamed, and that mental processes are in themselves unconscious and only reach the ego and come under its control through incomplete and untrustworthy perceptions - these two discoveries amount to a statement that *the ego is not master in its own house*. Together they represent the third blow to man's self-love, what I may call the *psychological* one. No wonder, then, that the ego does not look favourably upon psycho-analysis and obstinately refuses to believe in it.

Probably very few people can have realized the momentous significance for science and life of the recognition of unconscious mental processes. It was not psycho-analysis, however, let us hasten to add, which first took this step. There are famous philosophers who may be cited as forerunners - above all the great thinker Schopenhauer, whose unconscious 'Will' is equivalent to the mental instincts of psycho-analysis. It was this same thinker, moreover, who in words of unforgettable impressiveness admonished mankind of the importance, still so greatly under-estimated by it, of its sexual craving. Psycho-analysis has this advantage only, that it has not affirmed these two propositions which are so distressing to narcissism - the psychical importance of sexuality and the unconsciousness of mental life - on an *abstract* basis, but has demonstrated them in matters that touch every individual personally and force him to take up some attitude towards these problems. It is just for this reason, however, that it brings on itself the aversion and resistances which still hold back in awe before the great name of the philosopher.

A CHILDHOOD RECOLLECTION FROM *DICHTUNG UND WAHRHEIT*
(1917)

Intentionally left blank

A CHILDHOOD RECOLLECTION FROM *DICHTUNG UND WAHRHEIT*

'If we try to recollect what happened to us in the earliest years of childhood, we often find that we confuse what we have heard from others with what is really a possession of our own derived from what we ourselves have witnessed.' This remark is found on one of the first pages of Goethe's account of his life, which he began to write at the age of sixty. It is preceded only by some information about his birth, which 'took place on August 28, 1749, at midday on the stroke of twelve'. The stars were in a favourable conjunction and may well have been the cause of his survival, for at his entry into the world he was 'as though dead', and it was only after great efforts that he was brought to life. There follows on this a short description of the house and of the place in it where the children - he and his younger sister - best liked to play. After this, however, Goethe relates in fact only one single event which can be assigned to the 'earliest years of childhood' (the years up to four?) and of which he seems to have preserved a recollection of his own.

The account of it runs as follows: 'And three brothers (von Ochsenstein by name) who lived over the way became very fond of me; they were orphan sons of the late magistrate, and they took an interest in me and used to tease me in all sorts of ways.

'My people used to like to tell of all kinds of pranks in which these men, otherwise of a serious and retiring disposition, used to encourage me. I will quote only one of these exploits. The crockery-fair was just over, and not only had the kitchen been fitted up from it with what would be needed for some time to come, but miniature utensils of the same sort had been bought for us children to play with. One fine afternoon, when all was quiet in the house, I was playing with my dishes and pots in the hall' (a place which had already been described, opening on to the street) 'and, since this seemed to lead to nothing, I threw a plate into the street, and was overjoyed to see it go to bits so merrily. The von Ochsensteins, who saw how delighted I was and how joyfully I clapped my little hands, called out "Do it again!" I did not hesitate to sling out a pot on to the paving-stones, and then, as they kept crying "Another!", one after another all my little dishes, cooking-pots and pans. My neighbours continued to show their approval and I was highly delighted to be amusing them. But my stock was all used up, and still they cried "Another!" So I ran off straight into the kitchen and fetched the earthenware plates, which made an even finer show as they smashed to bits. And thus I ran backwards and forwards, bringing one plate after another, as I could reach them in turn from the dresser; and, as they were not content with that, I hurled every piece of crockery I could set hold of to the same destruction. Only later did someone come and interfere and put a stop to it all. The damage was done, and to make up for so much broken earthenware there was at least an amusing story, which the rascals who had been its instigators enjoyed to the end of their lives.'

In pre-analytic days it was possible to read this without finding occasion to pause and without feeling surprised, but later on the analytic conscience became active. We had formed definite opinions and expectations about the memories of earliest childhood, and would have liked to claim universal validity for them. It should not be a matter of indifference or entirely without meaning which detail of a child's life had escaped the general oblivion. It might on the contrary be conjectured that what had remained in memory was the most significant element in that whole period of life, whether it had possessed such an importance at the time, or whether it had gained subsequent importance from the influence of later events.

The high value of such childish recollections was, it is true, obvious only in a few cases. Generally they seemed indifferent, worthless even, and it remained at first incomprehensible why just these memories should have resisted amnesia; nor could the person who had preserved them for long years as part of his own store of memories see more in them than any stranger to whom he might relate them. Before their significance could be appreciated, a certain work of interpretation was necessary. This interpretation either showed that their content required to be replaced by some other content, or revealed that they were related to some other unmistakably important experiences and had appeared in their place as what are known as 'screen memories'.

In every psycho-analytic investigation of a life-history it is always possible to explain the meaning of the earliest childhood memories along these lines. Indeed, it usually happens that the very recollection to which the patient gives precedence, which he relates first, with which he introduces the story of his life, proves to be the most important, the very one that holds the key to the secret pages of his mind. But the little childish episode related in *Dichtung und Wahrheit* does not rise to our expectations. The ways and means that with our patients lead to interpretation are of course not available to us here; the episode does not seem in itself to admit of any traceable connection with important impressions at a later date. A mischievous trick with damaging effects on the household economy, carried out under the spur of outside encouragement, is certainly no fitting headpiece for all that Goethe has to tell us of his richly filled life. An impression of utter innocence and irrelevance clings to this childish memory, and it might be taken as a warning not to stretch the claims of psycho-analysis too far nor to apply it in unsuitable places.

The little problem, therefore, had long since slipped out of my mind, when one day chance brought me a patient in whom a similar childhood memory appeared in a clearer connection. He was a man of twenty-seven, highly educated and gifted, whose life at that time was entirely filled with a conflict with his mother that affected all his interests, and from the effects of which his capacity for love and his ability to lead an independent existence had suffered greatly. This conflict went far back into his childhood; certainly to his fourth year. Before that he had been a very weakly child, always ailing, and yet that sickly period was glorified into a paradise in his memory; for then he had had exclusive, uninterrupted possession of his mother's affection. When he was not yet four, a brother, who is still living, was born, and in his reaction to that disturbing event he became transformed into an obstinate, unmanageable boy, who perpetually provoked his mother's severity. More over, he never regained the right path.

When he came to me for treatment - by no means the least reason for his coming was that his mother, a religious bigot, had a horror of psycho-analysis - his jealousy of the younger brother (which had once actually been manifested as a murderous attack on the infant in its cradle) had long been forgotten. He now treated his brother with great consideration; but certain curious fortuitous actions of his (which involved sudden and severe injuries to favourite animals, like his sporting dog or birds which he had carefully reared,) were probably to be understood as echoes of these hostile impulses against the little brother.

Now this patient related that, at about the time of the attack on the baby he so much hated, he had thrown all the crockery he could lay hands on out of the window of their country house into the road - the very same thing that Goethe relates of his childhood in *Dichtung und Wahrheit*! I may remark that my patient was of foreign nationality and was not acquainted with German literature; he had never read Goethe's autobiography.

This communication naturally suggested to me that an attempt might be made to explain Goethe's childish memory on the lines forced upon us by my patient's story. But could the necessary conditions for this explanation be shown to exist in the poet's childhood? Goethe himself, it is true, makes the instigation of the von Ochsenstein brothers responsible for his childish prank. But from his own narrative it can be seen that these grown-up neighbours merely encouraged him to go on with what he was doing. The beginning was on his own initiative, and the reason he gives for this beginning - 'since this (the game) seemed to lead to nothing' - is surely, without any forcing of its meaning, a confession that at the time of writing it down and probably for many years previously he was not aware of any adequate motive for his behaviour.

It is well known that Johann Wolfgang and his sister Cornelia were the eldest survivors of a considerable family of very weakly children. Dr. Hanns Sachs has been so kind as to supply me with the following details concerning these brothers and sisters of Goethe's, who died in childhood:

(a) Hermann Jakob, baptized Monday, November 27, 1752; reached the age of six years and six weeks; buried January 13, 1759.

(b) Katharina Elisabetha, baptized Monday, September 9, 1754; buried Thursday, December 22, 1755. (One year and four months old).

(c) Johanna Maria, baptized Tuesday, March 29, 1757, and buried Saturday, August 11, 1759. (Two years and four months old)- (This was doubtless the very pretty and attractive little girl celebrated by her brother.)

(d) Georg Adolph, baptized Sunday, June 15, 1760; buried, eight months old, Wednesday, February 18, 1761.

Goethe's next youngest sister, Cornelia Friederica Christiana, was born on December 7, 1750, when he was fifteen months old. This slight difference in age almost excludes the possibility of her having been an object of jealousy. It is known that, when their passions awake, children never develop such violent reactions against the brothers and sisters they find already in existence, but direct their hostility against the newcomers. Nor is the scene we are endeavouring to interpret reconcilable with Goethe's tender age at the time of, or shortly after, Cornelia's birth.

At the time of the birth of the first little brother, Hermann Jakob, Johann Wolfgang was three and a quarter years old. Nearly two years later, when he was about five years old, the second sister was born. Both ages come under consideration in dating the episode of the throwing out of the crockery. The earlier is perhaps to be preferred; and it would best agree with the case of my patient, who was about three and a quarter years old at the birth of his brother.

Moreover, Goethe's brother Hermann Jakob, to whom we are thus led in our attempt at interpretation, did not make so brief a stay in the family nursery as the children born afterwards. One might feel some surprise that the autobiography does not contain a word of remembrance of him.¹ He was over six, and Johann Wolfgang was nearly ten, when he died. Dr. Hitschmann, who was kind enough to place his notes on this subject at my disposal, says:

'Goethe, too, as a little boy saw a younger brother die without regret. At least, according to Bettina Brentano his mother gave the following account: "It struck her as very extraordinary that he shed no tears at the death of his younger brother Jakob who was his playfellow; he seemed on the contrary to feel annoyance at the grief of his parents and sisters. When, later on, his mother asked the young rebel if he had not been fond of his brother, he ran into his room and brought out from under the bed a heap of papers on which lessons and little stories were written, saying that he had done all this to teach his brother." So it seems all the same that the elder brother enjoyed playing father to the younger and showing him his superiority.'

¹ (Footnote added 1924:) I take this opportunity of withdrawing an incorrect statement which should not have been made. In a later passage in this first volume the younger brother *is* mentioned and described. It occurs in connection with memories of the serious illnesses of childhood, from which this brother also suffered 'not a little'. 'He was a delicate child, quiet and self-willed, and we never had much to do with each other. Besides, he hardly survived the years of infancy.'

The opinion might thus be formed that the throwing of crockery out of the window was a symbolic action, or, to put it more correctly, a *magic* action, by which the child (Goethe as well as my patient) gave violent expression to his wish to get rid of a disturbing intruder. There is no need to dispute a child's enjoyment of smashing things; if an action is pleasurable in itself, that is not a hindrance but rather an inducement to repeat it in obedience to other purposes as well. It is unlikely, however, that it could have been the pleasure in the crash and the breaking which ensured the childish prank a lasting place in adult memory. Nor is there any objection to complicating the motivation of the action by adding a further factor. A child who breaks crockery knows quite well that he is doing something naughty for which grown-ups will scold him, and if he is not restrained by that knowledge, he probably has a grudge against his parents that he wants to satisfy; he wants to show naughtiness.

The pleasure in breaking and in broken things would be satisfied, too, if the child simply threw the breakable object on the ground. The hurling them out of the window into the street would still remain unexplained. This 'out!' seems to be an essential part of the magic action and to arise directly from its hidden meaning. The new baby must be got rid of - through the window, perhaps because he came in through the window. The whole action would thus be equivalent to the verbal response, already familiar to us, of a child who was told that the stork had brought a little brother. 'The stork can take him away again!' was his verdict.

All the same, we are not blind to the objections - apart from any internal uncertainties - against basing the interpretation of a childhood act on a single parallel. For this reason I had for years kept back my theory about the little scene in *Dichtung und Wahrheit*. Then one day I had a patient who began his analysis with the following remarks, which I set down word for word: 'I am the eldest of a family of eight or nine children.'¹ One of my earliest recollections is of my father sitting on the bed in his night-shirt, and telling me laughingly that I had a new brother. I was then three and three-quarters years old; that is the difference in age between me and my next younger brother. I know, too, that a short time after (or was it a year before?)² I threw a lot of things, brushes - or was it only one brush? - shoes and other things, out of the window into the street. I have a still earlier recollection. When I was two years old, I spent a night with my parents in a hotel bedroom at Linz on the way to the Salzkammergut. I was so restless in the night and made such a noise that my father had to beat me. '

After hearing this statement I threw all doubts to the winds. When in analysis two things are brought out one immediately after the other, as though in one breath, we have to interpret this proximity as a connection of thought. It was, therefore, as if the patient had said, 'Because I found that I had got a new brother, I shortly afterwards threw these things into the street.' The act of flinging the brushes, shoes and so on, out of the window must be recognized as a reaction to the birth of the brother. Nor is it a matter for regret that in this instance the objects thrown out were not crockery but other things, probably, anything the child could reach at the moment. - The hurling out (through the window into the street) thus proves to be the essential thing in the act, while the pleasure in the smashing and the noise, and the class of object on which 'execution is done', are variable and unessential points.

Naturally, the principle of there being a connection of thought must be applied as well to the patient's third childish recollection, which is the earliest, though it was put at the end of the short series. This can easily be done. Evidently the two-year-old child was so restless because he could not bear his parents being in bed together. On the journey it was no doubt impossible to avoid the child being a witness of this. The feelings which were aroused at that time in the jealous little boy left him with an embitterment against women which persisted and permanently interfered with the development of his capacity for love.

¹ A momentary error of a striking character. It was probably induced by the influence of the intention, which was already showing itself, to get rid of a brother. (Cf. Ferenczi, 1912, 'On Transitory Symptoms during Analysis'.)

² This doubt, attaching to the essential point of the communication for purposes of resistance, was shortly afterwards withdrawn by the patient of his own accord.

After making these two observations I expressed the opinion at a meeting of the Vienna Psycho-Analytical Society that occurrences of the same kind might be not infrequent among young children; in response, Frau Dr. von Hug-Hellmuth placed two further observations at my disposal, which I append here.

I

'At the age of about three and a half, little Erich quite suddenly acquired the habit of throwing everything he did not like out of the window. He also did it, however, with things that were not in his way and did not concern him. On his father's birthday - he was three years and four and a half months old - he snatched a heavy rolling-pin from the kitchen, dragged it into the living-room and threw it out of the window of the third-floor flat into the street. Some days later he sent after it the kitchen-pestle, and then a pair of heavy mountaineering boots of his father's, which he had first to take out of the cupboard.¹

'At that time his mother had a miscarriage, in the seventh or eighth month of pregnancy, and after that the child was "sweet and quiet and so good that he seemed quite changed". In the fifth or sixth month he repeatedly said to his mother, "Mummy, I'll jump on your tummy" - or, "I'll push your tummy in." And shortly before the miscarriage, in October, he said, "If I must have a brother, at least I don't want him till after Christmas."'

II

'A young lady of nineteen told me spontaneously that her earliest recollection was as follows: "I see myself, frightfully naughty, sitting under the table in the dining-room, ready to creep out. My cup of coffee is standing on the table - I can still see the pattern on the china quite plainly - and Granny comes into the room just as I am going to throw it out of the window.

"For the fact was that no one had been bothering about me, and in the meantime a skin had formed on the coffee, which was always perfectly dreadful to me and still is.

"On that day my brother, who is two and a half years younger than I am, was born, and so no one had had any time to spare for me.

"They always tell me that I was insupportable on that day: at dinner I threw my father's favourite glass on the floor, I dirtied my frock several times, and was in the worst temper from morning to night. In my rage I tore a bath-doll to pieces."

¹ 'He always chose heavy objects.'

These two cases scarcely call for a commentary. They establish without further analytic effort that the bitterness children feel about the expected or actual appearance of a rival finds expression in throwing objects out of the window and in other acts of naughtiness and destructiveness. In the first case the 'heavy objects' probably symbolized the mother herself, against whom the child's anger was directed so long as the new baby had not yet appeared. The three-and-a-half-year-old boy knew about his mother's pregnancy and had no doubt that she had got the baby in her body. 'Little Hans'¹ and his special dread of heavily loaded carts may be recalled here.² In the second case the very youthful age of the child, two and a half years, is noteworthy.

If we now return to Goethe's childhood memory and put in the place it occupies in *Dichtung und Wahrheit* what we believe we have obtained through observations of other children, a perfectly valid train of thought emerges which we should not otherwise have discovered. It would run thus: 'I was a child of fortune: destiny preserved my life, although I came into the world as though dead. Even more, destiny removed my brother, so that I did not have to share my mother's love with him.' The train of thought then goes on to someone else who died in those early days - the grandmother who lived like a quiet friendly spirit in another part of the house.

I have, however, already remarked elsewhere that if a man has been his mother's undisputed darling he retains throughout life the triumphant feeling, the confidence in success, which not seldom brings actual success along with it. And Goethe might well have given some such heading to his autobiography as: 'My strength has its roots in my relation to my mother.'

¹ Cf. 'Analysis of a Phobia in a Five-Year-Old Boy', (1909*b*)

² Further confirmation of this pregnancy-symbolism was given me some time ago by a lady of over fifty. She had often been told that as a little child, when she could hardly talk, she used to drag her father to the window in great agitation whenever a heavy furniture-van was passing along the street. In view of other recollections of the houses they had lived in, it became possible to establish that she was then younger than two and three quarter years. At about that time the brother next to her was born, and in consequence of this addition to the family a move was made. At about the same time, she often had an alarming feeling before going to sleep of something uncannily large, that came up to her, and 'her hands got so thick'.

LINES OF ADVANCE IN PSYCHO-ANALYTIC THERAPY
(1919)

Intentionally left blank

LINES OF ADVANCE IN PSYCHO-ANALYTIC THERAPY

GENTLEMEN, - As you know, we have never prided ourselves on the completeness and finality of our knowledge and capacity. We are just as ready now as we were earlier to admit the imperfections of our understanding, to learn new things and to alter our methods in any way that can improve them.

Now that we are met together once more after the long and difficult years of separation that we have lived through, I feel drawn to review the position of our therapeutic procedure - to which, indeed, we owe our place in human society - and to take a survey of the new directions in which it may develop.

We have formulated our task as physicians thus: to bring to the patient's knowledge the unconscious, repressed impulses existing in him, and, for that purpose, to uncover the resistances that oppose this extension of his knowledge about himself. Does the uncovering of these resistances guarantee that they will also be overcome? Certainly not always; but our hope is to achieve this by exploiting the patient's transference to the person of the physician, so as to induce him to adopt our conviction of the inexpediency of the repressive process established in childhood and of the impossibility of conducting life on the pleasure principle. I have set out elsewhere the dynamic conditions prevailing in the fresh conflict through which we lead the patient and which we substitute in him for his previous conflict - that of his illness. I have nothing at the moment to alter in that account.

The work by which we bring the repressed mental material into the patient's consciousness has been called by us psycho-analysis. Why 'analysis' - which means breaking up or separating out, and suggests an analogy with the work carried out by chemists on substances which they find in nature and bring into their laboratories? Because in an important respect there really is an analogy between the two. The patient's symptoms and pathological manifestations, like all his mental activities, are of a highly composite kind; the elements of this compound are at bottom motives, instinctual impulses. But the patient knows nothing of these elementary motives or not nearly enough. We teach him to understand the way in which these highly complicated mental formations are compounded; we trace the symptoms back to the instinctual impulses which motivate them; we point out to the patient these instinctual motives, which are present in his symptoms and of which he has hitherto been unaware, - just as a chemist isolates the fundamental substance, the chemical 'element', out of the salt in which it had been combined with other elements and in which it was unrecognizable. In the same way, as regards those of the patient's mental manifestations that were not considered pathological, we show him that he was only to a certain extent conscious of their motivation - that other instinctual impulses of which he had remained in ignorance had co-operated in producing them.

Again, we have thrown light on the sexual impulsions in man by separating them into their component elements; and when we interpret a dream we proceed by ignoring the dream as a whole and starting associations from its single elements.

This well-founded comparison of medical psycho-analytic activity with a chemical procedure might suggest a new direction for our therapy. We have *analysed* the patient - that is, separated his mental processes into their elementary constituents and demonstrated these instinctual elements in him singly and in isolation; what could be more natural than to expect that we should also help him to make a new and a better combination of them? You know that this demand has actually been put forward. We have been told that after an analysis of a sick mind a synthesis of it must follow. And, close upon this, concern has been expressed that the patient might be given too much analysis and too little synthesis; and there has then followed a move to put all the weight on this synthesis as the main factor in the psychotherapeutic effect, to see in it a kind of restoration of something that had been destroyed - destroyed, as it were, by vivisection.

But I cannot think, Gentlemen, that any new task is set us by this psycho-synthesis. If I allowed myself to be frank and uncivil I should say it was nothing but an empty phrase. I will limit myself to remarking that it is merely pushing a comparison so far that it ceases to have any meaning, or, if you prefer, that it is an unjustifiable exploitation of a name. A name, however, is only a label applied to distinguish a thing from other similar things, not a syllabus, a description of its content or a definition. And the two objects compared need only coincide at a single point and may be entirely different from each other in everything else. What is psychical is something so unique and peculiar to itself that no one comparison can reflect its nature. The work of psycho-analysis suggests analogies with chemical analysis, but it does so just as much with the intervention of a surgeon or the manipulations of an orthopaedist or the influence of an educator. The comparison with chemical analysis has its limitation: for in mental life we have to deal with trends that are under a compulsion towards unification and combination. Whenever we succeed in analysing a symptom into its elements, in freeing an instinctual impulse from one nexus, it does not remain in isolation, but immediately enters into a new one.¹

In actual fact, indeed, the neurotic patient presents us with a torn mind, divided by resistances. As we analyse it and remove the resistances, it grows together; the great unity which we call his ego fits into itself all the instinctual impulses which before had been split off and held apart from it. The psycho-synthesis is thus achieved during analytic treatment without our intervention, automatically and inevitably. We have created the conditions for it by breaking up the symptoms into their elements and by removing the resistances. It is not true that something in the patient has been divided into its components and is now quietly waiting for us to put it somehow together again.

Developments in our therapy, therefore, will no doubt proceed along other lines; first and foremost, along the one which Ferenczi, in his paper 'Technical Difficulties in an Analysis of Hysteria' (1919), has lately termed 'activity' on the part of the analyst.

¹ After all, something very similar occurs in chemical analysis. Simultaneously with the isolation of the various elements induced by the chemist, syntheses which are no part of his intention come about, owing to the liberation of the elective affinities of the substances concerned.

Let us at once agree upon what we mean by this activity. We have defined our therapeutic task as consisting of two things: making conscious the repressed material and uncovering the resistances. In that we are active enough, to be sure. But are we to leave it to the patient to deal alone with the resistances we have pointed out to him? Can we give him no other help in this besides the stimulus he gets from the transference? Does it not seem natural that we should help him in another way as well, by putting him into the mental situation most favourable to the solution of the conflict which is our aim? After all, what he can achieve depends, too, on a combination of external circumstances. Should we hesitate to alter this combination by intervening in a suitable manner? I think activity of such a kind on the part of the analysing physician is unobjectionable and entirely justified.

You will observe that this opens up a new field of analytic technique the working over of which will require close application and which will lead to quite definite rules of procedure. I shall not attempt to-day to introduce you to this new technique, which is still in the course of being evolved, but will content myself with enunciating a fundamental principle which will probably dominate our work in this field. It runs as follows: *Analytic treatment should be carried through, as far as is possible, under privation - in a state of abstinence.*

How far it is possible to show that I am right in this must be left to a more detailed discussion. By abstinence, however, is not to be understood doing without any and every satisfaction - that would of course not be practicable; nor do we mean what it popularly connotes, refraining from sexual intercourse; it means something else which has far more to do with the dynamics of falling ill and recovering.

You will remember that it was a *frustration* that made the patient ill, and that his symptoms serve him as substitutive satisfactions. It is possible to observe during the treatment that every improvement in his condition reduces the rate at which he recovers and diminishes the instinctual force impelling him towards recovery. But this instinctual force is indispensable; reduction of it endangers our aim - the patient's restoration to health. What, then, is the conclusion that forces itself inevitably upon us? Cruel though it may sound, we must see to it that the patient's suffering, to a degree that is in some way or other effective, does not come to an end prematurely. If, owing to the symptoms having been taken apart and having lost their value, his suffering becomes mitigated, we must reinstate it elsewhere in the form of some appreciable privation; otherwise we run the danger of never achieving any improvements except quite insignificant and transitory ones.

As far as I can see, the danger threatens from two directions in especial. On the one hand, when the illness has been broken down by the analysis, the patient makes the most assiduous efforts to create for himself in place of his symptoms new substitutive satisfactions, which now lack the feature of suffering. He makes use of the enormous capacity for displacement possessed by the now partly liberated libido, in order to cathect with libido and promote to the position of substitutive satisfactions the most diverse kinds of activities, preferences and habits, not excluding some that have been his already. He continually finds new distractions of this kind, into which the energy necessary to carrying on the treatment escapes, and he knows how to keep them secret for a time. It is the analyst's task to detect these divergent paths and to require him every time to abandon them, however harmless the activity which leads to satisfaction may be in itself. The half-recovered patient may also enter on less harmless paths - as when, for instance, if he is a man, he seeks prematurely to attach himself to a woman. It may be observed, incidentally, that unhappy marriage and physical infirmity are the two things that most often supersede a neurosis. They satisfy in particular the sense of guilt (need for punishment) which makes many patients cling so fast to their neuroses. By a foolish choice in marriage they punish themselves; they regard a long organic illness as a punishment by fate and thereafter often cease to keep up their neurosis.

In all such situations activity on the part of the physician must take the form of energetic opposition to premature substitutive satisfactions. It is easier for him, however, to prevent the *second* danger which jeopardizes the propelling force of the analysis, though it is not one to be under-estimated. The patient looks for his substitutive satisfactions above all in the treatment itself, in his transference-relationship with the physician; and he may even strive to compensate himself by this means for all the other privations laid upon him. Some concessions must of course be made to him, greater or less, according to the nature of the case and the patient's individuality. But it is not good to let them become too great. Any analyst who out of the fullness of his heart, perhaps, and his readiness to help, extends to the patient all that one human being may hope to receive from another, commits the same economic error as that of which our non-analytic institutions for nervous patients are guilty. Their one aim is to make everything as pleasant as possible for the patient, so that he may feel well there and be glad to take refuge there again from the trials of life. In so doing they make no attempt to give him more strength for facing life and more capacity for carrying out his actual tasks in it. In analytic treatment all such spoiling must be avoided. As far as his relations with the physician are concerned, the patient must be left with unfulfilled wishes in abundance. It is expedient to deny him precisely those satisfactions which he desires most intensely and expresses most importunately.

I do not think I have exhausted the range of desirable activity on the part of the physician in saying that a condition of privation is to be kept up during the treatment. Activity in another direction during analytic treatment has already, as you will remember, been a point at issue between us and the Swiss school. We refused most emphatically to turn a patient who puts himself into our hands in search of help into our private property, to decide his fate for him, to force our own ideals upon him, and with the pride of a Creator to form him in our own image and see that it is good. I still adhere to this refusal, and I think that this is the proper place for the medical discretion which we have had to ignore in other connections. I have learnt by experience, too, that such a far-reaching activity towards patients is not in the least necessary for therapeutic purposes. For I have been able to help people with whom I had nothing in common - neither race, education, social position nor outlook upon life in general - without affecting their individuality. At the time of the controversy I have just spoken of, I had the impression, to be sure, that the objections of our spokesmen - I think it was Ernest Jones who took the chief part - were too harsh and uncompromising. We cannot avoid taking some patients for treatment who are so helpless and incapable of ordinary life that for them one has to combine analytic with educative influence; and even with the majority, occasions now and then arise in which the physician is bound to take up the position of teacher and mentor. But it must always be done with great caution, and the patient should be educated to liberate and fulfil his own nature, not to resemble ourselves.

Our honoured friend, J. J. Putnam, in the land of America which is now so hostile to us, must forgive us if we cannot accept his proposal either - namely that psycho-analysis should place itself in the service of a particular philosophical outlook on the world and should urge this upon the patient for the purpose of ennobling his mind. In my opinion, this is after all only to use violence, even though it is overlaid with the most honourable motives.

Lastly, another quite different kind of activity is necessitated by the gradually growing appreciation that the various forms of disease treated by us cannot all be dealt with by the same technique. It would be premature to discuss this in detail, but I can give two examples of the way in which a new kind of activity comes into question. Our technique grew up in the treatment of hysteria and is still directed principally to the cure of that affection. But the phobias have already made it necessary for us to go beyond our former limits. One can hardly master a phobia if one waits till the patient lets the analysis influence him to give it up. He will never in that case bring into the analysis the material indispensable for a convincing resolution of the phobia. One must proceed differently. Take the example of agoraphobia; there are two classes of it, one mild, the other severe. Patients belonging to the first class suffer from anxiety when they go into the street by themselves, but they have not yet given up going out alone on that account; the others protect themselves from the anxiety by altogether ceasing to go about alone. With these last one succeeds only when one can induce them by the influence of the analysis to behave like phobic patients of the first class - that is, to go into the street and to struggle with their anxiety while they make the attempt. One starts, therefore, by moderating the phobia so far; and it is only when that has been achieved at the physician's demand that the associations and memories come into the patient's mind which enable the phobia to be resolved.

In severe cases of obsessive acts a passive waiting attitude seems even less indicated. Indeed in general these cases incline to an 'asymptotic' process of recovery, an interminable protraction of the treatment. Their analysis is always in danger of bringing to light a great deal and changing nothing. I think there is little doubt that here the correct technique can only be to wait until the treatment itself has become a compulsion, and then with this counter-compulsion forcibly to suppress the compulsion of the disease. You will understand, however, that these two instances I have given you are only samples of the new developments towards which our therapy is tending.

And now in conclusion I will cast a glance at a situation which belongs to the future - one that will seem fantastic to many of you, but which I think, nevertheless, deserves that we should be prepared for it in our minds. You know that our therapeutic activities are not very far-reaching. There are only a handful of us, and even by working very hard each one can devote himself in a year to only a small number of patients. Compared to the vast amount of neurotic misery which there is in the world, and perhaps need not be, the quantity we can do away with is almost negligible. Besides this, the necessities of our existence limit our work to the well-to-do classes, who are accustomed to choose their own physicians and whose choice is diverted away from psycho-analysis by all kinds of prejudices. At present we can do nothing for the wider social strata, who suffer extremely seriously from neuroses.

Now let us assume that by some kind of organization we succeeded in increasing our numbers to an extent sufficient for treating a considerable mass of the population. On the other hand, it is possible to foresee that at some time or other the conscience of society will awake and remind it that the poor man should have just as much right to assistance for his mind as he now has to the life-saving help offered by surgery; and that the neuroses threaten public health no less than tuberculosis, and can be left as little as the latter to the impotent care of individual members of the community. When this happens, institutions or out-patient clinics will be started, to which analytically-trained physicians will be appointed, so that men who would otherwise give way to drink, women who have nearly succumbed under their burden of privations, children for whom there is no choice but between running wild or neurosis, may be made capable, by analysis, of resistance and of efficient work. Such treatments will be free. It may be a long time before the State comes to see these duties as urgent. Present conditions may delay its arrival even longer. Probably these institutions will first be started by private charity. Some time or other, however, it must come to this.

We shall then be faced by the task of adapting our technique to the new conditions. I have no doubt that the validity of our psychological assumptions will make its impression on the uneducated too, but we shall need to look for the simplest and most easily intelligible ways of expressing our theoretical doctrines. We shall probably discover that the poor are even less ready to part with their neuroses than the rich, because the hard life that awaits them if they recover offers them no attraction, and illness gives them one more claim to social help. Often, perhaps, we may only be able to achieve anything by combining mental assistance with some material support, in the manner of the Emperor Joseph. It is very probable, too, that the large-scale application of our therapy will compel us to alloy the pure gold of analysis freely with the copper of direct suggestion; and hypnotic influence, too, might find a place in it again, as it has in the treatment of war neuroses. But, whatever form this psychotherapy for the people may take, whatever the elements out of which it is compounded, its most effective and most important ingredients will assuredly remain those borrowed from strict and untendentious psycho-analysis.

ON THE TEACHING OF PSYCHO-ANALYSIS IN UNIVERSITIES
(1919)

Intentionally left blank

ON THE TEACHING OF PSYCHO-ANALYSIS IN UNIVERSITIES

The question of the advisability of teaching psycho-analysis in Universities may be considered from two points of view: that of psycho-analysis and that of the University.

(1) The inclusion of psycho-analysis in the University curriculum would no doubt be regarded with satisfaction by every psycho-analyst. At the same time it is clear that the psycho-analyst can dispense entirely with the University without any loss to himself. For what he needs in the matter of theory can be obtained from the literature of the subject and, going more deeply, at the scientific meetings of the psycho-analytic societies as well as by personal contact with their more experienced members. As regards practical experience, apart from what he gains from his own personal analysis, he can acquire it by carrying out treatments, provided that he can get supervision and guidance from recognized psycho-analysts.

The fact that an organization of this kind exists is actually due to the exclusion of psycho-analysis from Universities. And it is therefore evident that these arrangements will continue to perform an effective function so long as this exclusion persists.

(2) So far as the Universities are concerned, the question depends on their deciding whether they are willing to attribute any value at all to psycho-analysis in the training of physicians and scientists. If so, the further problem remains of how it is to be incorporated into the regular educational framework.

The importance of psycho-analysis for the whole of medical and academic training is based on the following facts:

(a) This training has been quite rightly criticized during the last few decades for the one-sided way in which it directs the student into the fields of anatomy, physics and chemistry, while failing, on the other hand, to make plain to him the significance of mental factors in the different vital functions as well as in illnesses and their treatment. This short-coming in medical education makes itself felt later as a flagrant blind spot in the physician. This will not only show itself in his lack of interest in the most absorbing problems of human life, whether healthy or diseased, but will also render him unskilful in his treatment of patients, so that even quacks and 'healers' will have a greater effect on them than he does.

This obvious deficiency led some time ago to the inclusion in the University curriculum of courses of lectures on medical psychology. But so long as these lectures were based on academic psychology or on experimental psychology (which deals only with questions of detail), they were unable to meet the requirements of the student's training; nor could they bring him any nearer to the problems of life in general or to those of his profession. For these reasons the place occupied by this kind of medical psychology in the curriculum proved insecure.

A course of lectures on psycho-analysis, on the other hand, would certainly answer these requirements. Before coming to psycho-analysis proper, an introductory course would be needed, which would deal in detail with the relations between mental and physical life - the basis of all kinds of psychotherapy -, would describe the various kinds of suggestive procedures, and would finally show how psycho-analysis constitutes the outcome and culmination of all the earlier methods of mental treatment. Psycho-analysis, in fact, more than any other system, is fitted for teaching psychology to the medical student.

(b) Another of the functions of psycho-analysis should be to afford a preparation for the study of psychiatry. This, in its present shape, is exclusively descriptive in character; it merely teaches the student to recognize a series of pathological entities, enabling him to distinguish which are incurable and which are dangerous to the community. Its sole connection with the other branches of medical science lies in organic aetiology - that is, in its anatomical findings; but it offers not the slightest understanding of the facts observed. Such an understanding can be furnished only by a depth-psychology.

In America, according to the best of my information, it has already been recognized that psycho-analysts (the first attempt at a depth-psychology) has made successful inroads into this unexplored region of psychiatry. Many medical schools in that country, accordingly, have already organized courses of psycho-analysis as an introduction to psychiatry.

The teaching of psycho-analysis would have to proceed in two stages: an elementary course, designed for all medical students, and a course of specialized lectures for psychiatrists.

(c) In the investigation of mental processes and intellectual functions, psycho-analysis pursues a specific method of its own. The application of this method is by no means confined to the field of psychological disorders, but extends also to the solution of problems in art, philosophy and religion. In this direction it has already yielded several new points of view and thrown valuable light on such subjects as the history of literature, on mythology, on the history of civilizations and on the philosophy of religion. Thus the general psycho-analytic course should be thrown open to the students of these branches of learning as well. The fertilizing effects of psycho-analytic thought on these other disciplines would certainly contribute greatly towards forging a closer link, in the sense of a *universitas literarum*, between medical science and the branches of learning which lie within the sphere of philosophy and the arts.

To sum up, it may be asserted that a University stands only to gain by the inclusion in its curriculum of the teaching of psycho-analysis. That teaching, it is true, can only be given in a dogmatic and critical manner, by means of theoretical lectures; for these lectures will allow only a very restricted opportunity for carrying out experiments or for practical demonstrations. For the purposes of research, it should be sufficient for teachers of psycho-analysis to have access to an out-patient department for the supply of the necessary material in the form of 'neurotic' patients. For psycho-analytic psychiatry, a mental in-patient department would also have to be available.

Consideration, lastly, must be given to the objection that, along these lines, the medical student will never learn psycho-analysis proper. This is indeed true, if we have in mind the actual practice of psycho-analysis. But for the purposes we have in view it will be enough if he learns something *about* psycho-analysis and something *from* it. After all, University training does not equip the medical student to be a skilled surgeon; and no one who chooses surgery as a profession can avoid further training in the form of several years of work in a surgical department of a hospital.

‘A CHILD IS BEING BEATEN’
A CONTRIBUTION TO THE STUDY OF THE ORIGIN OF SEXUAL PERVERSIONS
(1919)

Intentionally left blank

‘A CHILD IS BEING BEATEN’
A CONTRIBUTION TO THE STUDY OF THE ORIGIN OF SEXUAL PERVERSIONS

I

It is surprising how often people who seek analytic treatment for hysteria or an obsessional neurosis confess to having indulged in the phantasy: ‘A child is being beaten.’ Very probably there are still more frequent instances of it among the far greater number of people who have not been obliged to come to analysis by manifest illness.

The phantasy has feelings of pleasure attached to it, and on their account the patient has reproduced it on innumerable occasions in the past or may even still be doing so. At the climax of the imaginary situation there is almost invariably a masturbatory satisfaction - carried out, that is to say, on the genitals. At first this takes place voluntarily, but later on it does so in spite of the patient’s efforts, and with the characteristics of an obsession.

It is only with hesitation that this phantasy is confessed to. Its first appearance is recollected with uncertainty. The analytic treatment of the topic is met by unmistakable resistance. Shame and a sense of guilt are perhaps more strongly excited in this connection than when similar accounts are given of memories of the beginning of sexual life. Eventually it becomes possible to establish that the first phantasies of the kind were entertained very early in life: certainly before school age, and not later than in the fifth or sixth year. When the child was at school and saw other children being beaten by the teacher, then, if the phantasies had become dormant, this experience called them up again, or, if they were still present, it reinforced them and noticeably modified their content. From that time forward it was ‘an indefinite number’ of children that were being beaten. The influence of the school was so clear that the patients concerned were at first tempted to trace back their beating-phantasies exclusively to these impressions of school life, which dated from later than their sixth year. But it was never possible for them to maintain that position; the phantasies had already been in existence before.

Though in the higher forms at school the children were no longer beaten, the influence of such occasions was replaced and more than replaced by the effects of reading, of which the importance was soon to be felt. In my patients' *milieu* it was almost always the same books whose contents gave a new stimulus to the beating-phantasies: those accessible to young people, such as what was known as the '*Bibliothèque rose*', *Uncle Tom's Cabin*, etc. The child began to compete with these works of fiction by producing his own phantasies and by constructing a wealth of situations and institutions, in which children were beaten, or were punished and disciplined in some other way, because of their naughtiness and bad behaviour.

This fantasy - 'a child is being beaten' - was invariably cathected with a high degree of pleasure and had its issue in an act of pleasurable auto-erotic satisfaction. It might therefore be expected that the sight of another child being beaten at school would also be a source of similar enjoyment. But as a matter of fact this was never so. The experience of real scenes of beating at school produced in the child who witnessed them a peculiarly excited feeling which was probably of a mixed character and in which repugnance had a large share. In a few cases the real experience of the scenes of beating was felt to be intolerable. Moreover, it was always a condition of the more sophisticated phantasies of later years that the punishment should do the children no serious injury.

The question was bound to arise of what relation there might be between the importance of the beating-phantasies and the part that real corporal punishment might have played in the child's bringing up at home. It was impossible, on account of the one-sidedness of the material, to confirm the first suspicion that the relation was an inverse one. The individuals from whom the data for these analyses were derived were very seldom beaten in their childhood, or were at all events not brought up by the help of the rod. Naturally, however, each of these children was bound to have become aware at one time or another of the superior physical strength of its parents or educators; the fact that in every nursery the children themselves at times come to blows requires no special emphasis.

As regards the early and simple phantasies which could not be obviously traced to the influence of school impressions or of scenes taken from books, further information would have been welcome. Who was the child that was being beaten? The one who was himself producing the phantasy or another? Was it always the same child or as often as not a different one? Who has it that was beating the child? A grown-up person? And if so, who? Or did the child imagine that he himself was beating another one? Nothing could be ascertained that threw any light upon all these questions - only the hesitant reply: 'I know nothing more about it: a child is being beaten.'

Enquiries as to the sex of the child that was being beaten met with more success, but none the less brought no enlightenment. Sometimes the answer was: 'Always boys', or 'Only girls'; more often it was: 'I don't know, or 'It doesn't matter which'. But the point to which the questions were directed, the discovery of some constant relation between the sex of the child producing the phantasy and that of the child that was being beaten, was never established. Now and again another characteristic detail of the content of the phantasy came to light: 'A small child is being beaten on its naked bottom.'

In these circumstances it was impossible at first even to decide whether the pleasure attaching to the beating-phantasy was to be described as sadistic or masochistic.

II

A phantasy of this kind, arising, perhaps from accidental causes, in early childhood and retained for the purpose of auto-erotic satisfaction, can, in the light of our present knowledge, only be regarded as a primary trait of perversion. One of the components of the sexual function has, it seems, developed in advance of the rest, has made itself prematurely independent, has undergone fixation and in consequence been withdrawn from the later processes of development, and has in this way given evidence of a peculiar and abnormal constitution in the individual. We know that an infantile perversion of this sort need not persist for a whole lifetime; later on it can be subjected to repression, be replaced by a reaction-formation, or be transformed by sublimation. (It is possible that sublimation arises out of some special process which would be held back by repression.) But if these processes do not take place, then the perversion persists to maturity; and whenever we find a sexual aberration in adults - perversion, fetishism, inversion - we are justified in expecting that anamnestic investigation will reveal an event such as I have suggested, leading to a fixation in childhood. Indeed, long before the days of psycho-analysis, observers like Binet were able to trace the strange sexual aberrations of maturity back to similar impressions and to precisely the same period of childhood, namely, the fifth or sixth year. But at this point the enquiry was confronted with the limitations of our knowledge; for the impressions that brought about the fixation were without any traumatic force. They were for the most part commonplace and unexciting to other people. It was impossible to say why the sexual impulse had undergone fixation particularly upon them. It was possible, however, to look for their significance in the fact that they offered an occasion for fixation (even though it was an accidental one) to precisely that component which was prematurely developed and ready to press forward. We had in any case to be prepared to come to a provisional end somewhere or other in tracing back the train of causal connection; and the congenital constitution seemed exactly to correspond with what was required for a stopping-place of that kind.

If the sexual component which has broken loose prematurely is the sadistic one, then we may expect, on the basis of knowledge derived from other sources, that its subsequent repression will result in a disposition to an obsessional neurosis. This expectation cannot be said to be contradicted by the results of enquiry. The present short paper is based on the exhaustive study of six cases (four female and two male). Of these, two were cases of obsessional neurosis; one extremely severe and incapacitating, the other of moderate severity and quite well accessible to influence. There was also a third case which at all events exhibited clearly marked individual traits of obsessional neurosis. The fourth case, it must be admitted, was one of straightforward hysteria, with pains and inhibitions; and the fifth patient, who had come to be analysed merely on account of indecisiveness in life, would not have been classified at all by coarse clinical diagnosis, or would have been dismissed as 'psychasthenic'. There is no need for feeling disappointed over these statistics. In the first place, we know that not every disposition is necessarily developed into a disorder; in the second place, we ought to be content to explain the facts before us, and ought as a rule to avoid the additional task of making it clear why something has *not* taken place.

The present state of our knowledge would allow us to make our way so far and no further towards the comprehension of beating-phantasies. In the mind of the analytic physician, it is true, there remains an uneasy suspicion that this is not a final solution of the problem. He is obliged to admit to himself that to a great extent these phantasies subsist apart from the rest of the content of a neurosis, and find no proper place in its structure. But impressions of this kind, as I know from my own experience, are only too willingly put on one side.

III

Strictly considered - and why should this question not be considered with all possible strictness? - analytic work deserves to be recognized as genuine psycho-analysis only when it has succeeded in removing the amnesia which conceals from the adult his knowledge of his childhood from its beginning (that is, from about the second to the fifth year). This cannot be said among analysts too emphatically or repeated too often. The motives for disregarding this reminder are, indeed, intelligible. It would be desirable to obtain practical results in a shorter period and with less trouble. But at the present time theoretical knowledge is still far more important to all of us than therapeutic success, and anyone who neglects childhood analysis is bound to fall into the most disastrous errors. The emphasis which is laid here upon the importance of the earliest experiences does not imply any underestimation of the influence of later ones. But the later impressions of life speak loudly enough through the mouth of the patient, while it is the physician who has to raise his voice on behalf of the claims of childhood.

It is in the years of childhood between the ages of two and four or five that the congenital libidinal factors are first awakened by actual experiences and become attached to certain complexes. The beating-phantasies which are now under discussion show themselves only towards the end of this period or after its termination. So it may quite well be that they have an earlier history, that they go through a process of development, that they represent an end-product and not an initial manifestation.

This suspicion is confirmed by analysis. A systematic application of it shows that beating-phantasies have a historical development which is by no means simple, and in the course of which they are changed in most respects more than once as regards their relation to the author of the phantasy, and as regards their object, their content and their significance.

In order to make it easier to follow these transformations in beating-phantasies I shall now venture to confine my descriptions to the female cases, which, since they are four as against two, in any case constitute the greater part of my material. Moreover, beating-phantasies in men are connected with another subject, which I shall leave on one side in this paper. In my description I shall be careful to avoid being more schematic than is inevitable for the presentation of an average case. If then on further observation a greater complexity of circumstances should come to light, I shall nevertheless be sure of having before us a typical occurrence, and one, moreover, that is not of an uncommon kind.

The first phase of beating-phantasies among girls, then, must belong to a very early period of childhood. Some features remain curiously indefinite, as though they were a matter of indifference. The scanty information given by the patients in their first statement, 'a child is being beaten', seems to be justified in respect to this phase. But another of their features can be established with certainty, and to the same effect in every case. The child being beaten is never the one producing the phantasy, but is invariably another child, most often a brother or a sister if there is any. Since this other child may be a boy or a girl, there is no constant relation between the sex of the child producing the phantasy and that of the child being beaten. The phantasy, then, is certainly not masochistic. It would be tempting to call it sadistic, but one cannot neglect the fact that the child producing the phantasy is never doing the beating herself. The actual identity of the person who does the beating remains obscure at first. Only this much can be established: it is not a child but an adult. Later on this indeterminate grown-up person becomes recognizable clearly and unambiguously as the (girl's) *father*.

This first phase of the beating-phantasy is therefore completely represented by the phrase: '*My father is beating the child.*' I am betraying a great deal of what is to be brought forward later when instead of this I say: 'My father is beating the child *whom I hate.*' Moreover, one may hesitate to say whether the characteristics of a 'phantasy' can yet be ascribed to this first step towards the later beating-phantasy. It is perhaps rather a question of recollections of events which have been witnessed, or of desires which have arisen on various occasions. But these doubts are of no importance.

Profound transformations have taken place between this first phase and the next. It is true that the person beating remains the same (that is, the father); but the child who is beaten has been changed into another one and is now invariably the child producing the phantasy. The phantasy is accompanied by a high degree of pleasure, and has now acquired a significant content, with the origin of which we shall be concerned later. Now, therefore, the wording runs: '*I am being beaten by my father.*' It is of an unmistakably masochistic character.

This second phase is the most important and the most momentous of all. But we may say of it in a certain sense that it has never had a real existence. It is never remembered, it has never succeeded in becoming conscious. It is a construction of analysis, but it is no less a necessity on that account.

The third phase once more resembles the first. It has the wording which is familiar to us from the patient's statement. The person beating is never the father, but is either left undetermined just as in the first phase, or turns in a characteristic way into a representative of the father, such as a teacher. The figure of the child who is producing the beating-phantasy no longer itself appears in it. In reply to pressing enquiries the patients only declare: 'I am probably looking on.' Instead of the one child that is being beaten, there are now a number of children present as a rule. Most frequently it is boys who are being beaten (in girls' phantasies), but none of them is personally known to the subject. The situation of being beaten, which was originally simple and monotonous, may go through the most complicated alterations and elaborations; and punishments and humiliations of another kind may be substituted for the beating itself. But the essential characteristic which distinguishes even the simplest phantasies of this phase from those of the first, and which establishes the connection with the intermediate phase, is this: the phantasy now has strong and unambiguous sexual excitement attached to it, and so provides a means for masturbatory satisfaction. But this is precisely what is puzzling. By what path has the phantasy of strange and unknown boys being beaten (a phantasy which has by this time become sadistic) found its way into the permanent possession of the little girl's libidinal trends?

Nor can we conceal from ourselves that the interrelations and sequence of the three phases of the beating-phantasy, as well as all its other peculiarities, have so far remained quite unintelligible.

IV

If the analysis is carried through the early period to which the beating-phantasies are referred and from which they are recollected, it shows us the child involved in the agitations of its parental complex.

The affections of the little girl are fixed on her father, who has probably done all he could to win her love, and in this way has sown the seeds of an attitude of hatred and rivalry towards her mother. This attitude exists side by side with a current of affectionate dependence on her, and as years go on it may be destined to come into consciousness more and more clearly and forcibly, or else to give an impetus to an excessive reaction of devotion to her. But it is not with the girl's relation to her mother that the beating-phantasy is connected. There are other children in the nursery, only a few years older or younger, who are disliked on all sorts of other grounds, but chiefly because the parents' love has to be shared with them, and for this reason they are repelled with all the wild energy characteristic of the emotional life of those years. If the child in question is a younger brother or sister (as in three of my four cases) it is despised as well as hated; yet it attracts to itself the share of affection which the blinded parents are always ready to give the youngest child, and this is a spectacle the sight of which cannot be avoided. One soon learns that being beaten, even if it does not hurt very much, signifies a deprivation of love and a humiliation. And many children who believed themselves securely enthroned in the unshakable affection of their parents have by a single blow been cast down from all the heavens of their imaginary omnipotence. The idea of the father beating this hateful child is therefore an agreeable one, quite apart from whether he has actually been seen doing so. It means: 'My father does not love this other child, *he loves only me.*'

This then is the content and meaning of the beating-phantasy in its first phase. The phantasy obviously gratifies the child's jealousy and is dependent upon the erotic side of its life, but is also powerfully reinforced by the child's egoistic interests. Doubt remains, therefore, whether the phantasy ought to be described as purely 'sexual', nor can one venture to call it 'sadistic'.

As is well known, all the signs on which we are accustomed to base our distinctions tend to lose their clarity as we come nearer to the source. So perhaps we may say in terms recalling the prophecy made by the Three Witches to Banquo: 'Not clearly sexual, not in itself sadistic, but yet the stuff from which both will later come.' In any case, however, there is no ground for suspecting that in this first phase the phantasy is already at the service of an excitation which involves the genitals and finds its outlet in a masturbatory act.

It is clear that the child's sexual life has reached the stage of genital organization, now that its incestuous love has achieved this premature choice of an object. This can be demonstrated more easily in the case of boys, but is also indisputable in the case of girls. Something like a premonition of what are later to be the final and normal sexual aims governs the child's libidinal trends. We may justly wonder why this should be so, but we may regard it as a proof of the fact that the genitals have already begun playing their part in the process of excitation. With boys the wish to beget a child from their mother is never absent, with girls the wish to have a child by their father is equally constant; and this in spite of their being completely incapable of forming any clear idea of the means for fulfilling these wishes. The child seems to be convinced that the genitals have something to do with the matter, even though in its constant brooding it may look for the essence of the presumed intimacy between its parents in relations of another sort, such as in their sleeping together, micturating in each other's presence, etc.; and material of the latter kind can be more easily apprehended in verbal images than the mystery that is connected with the genitals.

But the time comes when this early blossoming is nipped by the frost. None of these incestuous loves can avoid the fate of repression. They may succumb to it on the occasion of some discoverable external event which leads to disillusionment - such as unexpected slights, the unwelcome birth of a new brother or sister (which is felt as faithlessness), etc.; or the same thing may happen owing to internal conditions apart from any such events, perhaps simply because their yearning remains unsatisfied too long. It is unquestionably true that such events are not the *effective* causes, but that these love-affairs are bound to come to grief sooner or later, though we cannot say on what particular stumbling block. Most probably they pass away because their time is over, because the children have entered upon a new phase of development in which they are compelled to recapitulate from the history of mankind the repression of an incestuous object-choice, just as at an earlier stage they were obliged to effect an object-choice of that very sort.¹ In the new phase no mental product of the incestuous love-impulses that is present unconsciously is taken over by consciousness; and anything that has already come into consciousness is expelled from it. At the same time as this process of repression takes place, a sense of guilt appears. This is also of unknown origin, but there is no doubt whatever that it is connected with the incestuous wishes, and that it is justified by the persistence of those wishes in the unconscious.²

¹ Compare the part played by Fate in the myth of Oedipus.

² [Footnote added 1924:] See the continuation of this line of thought in 'The Dissolution of the Oedipus Complex' (1924d).

The phantasy of the period of incestuous love had said: 'He (my father) loves only me, and not the other child, for he is beating it.' The sense of guilt can discover no punishment more severe than the reversal of this triumph: 'No, he does not love you, for he is beating you.' In this way the phantasy of the second phase, that of being beaten by her father, is a direct expression of the girl's sense of guilt, to which her love for her father has now succumbed. The phantasy, therefore, has become masochistic. So far as I know, this is always so; a sense of guilt is invariably the factor that transforms sadism into masochism. But this is certainly not the whole content of masochism. The sense of guilt cannot have won the field alone; a share must also fall to the love-impulse. We must remember that we are dealing with children in whom the sadistic component was able for constitutional reasons to develop prematurely and in isolation. We need not abandon this point of view. It is precisely such children who find it particularly easy to hark back to the pregenital, sadistic-anal organization of their sexual life. If the genital organization, when it has scarcely been effected, is met by repression, the result is not only that every psychical representation of the incestuous love becomes unconscious, or remains so, but there is another result as well: a regressive debasement of the genital organization itself to a lower level. 'My father loves me' was meant in a genital sense; owing to the regression it is turned into 'My father is beating me (I am being beaten by my father)'. This being beaten is now a convergence of the sense of guilt and sexual love. *It is not only the punishment for the forbidden genital relation, but also the regressive substitute for that relation*, and from this latter source it derives the libidinal excitation which is from this time forward attached to it, and which finds its outlet in masturbatory acts. Here for the first time we have the essence of masochism.

This second phase - the child's phantasy of being itself beaten by its father - remains unconscious as a rule, probably in consequence of the intensity of the repression. I cannot explain why nevertheless in one of my six cases, that of a male, it was consciously remembered. This man, now grown up, had preserved the fact clearly in his memory that he used to employ the idea of being beaten by his mother for the purpose of masturbation, though to be sure he soon substituted for his own mother the mothers of his school-fellows or other women who in some way resembled her. It must not be forgotten that when a boy's incestuous phantasy is transformed into the corresponding masochistic one, one more reversal has to take place than in the case of a girl, namely the substitution of passivity for activity; and this additional degree of distortion may save the phantasy from having to remain unconscious as a result of repression. In this way the sense of guilt would be satisfied by regression instead of by repression. In the female cases the sense of guilt, in itself perhaps more exacting, could be appeased only by a combination of the two.

In two of my four female cases an elaborate superstructure of day-dreams, which was of great significance for the life of the person concerned, had grown up over the masochistic beating-phantasy. The function of this superstructure was to make possible a feeling of satisfied excitation, even though the masturbatory act was abstained from. In one of these cases the content - being beaten by the father - was allowed to venture again into consciousness, so long as the subject's own ego was made unrecognizable by a thin disguise. The hero of these stories was invariably beaten (or later only punished, humiliated, etc.) by his father.

I repeat, however, that as a rule the phantasy remains unconscious, and can only be reconstructed in the course of the analysis. This fact perhaps vindicates patients who say they remember that with them masturbation made its appearance before the third phase of the beating-phantasy (shortly to be discussed), and that this phase was only a later addition, made perhaps under the impression of scenes at school. Every time I have given credit to these statements I have felt inclined to assume that the masturbation was at first under the dominance of unconscious phantasies and that conscious ones were substituted for them later.

I look upon the beating-phantasy in its familiar third phase, which is its final form, as a substitute of this sort. Here the child who produces the phantasy appears almost as a spectator, while the father persists in the shape of a teacher or some other person in authority. The phantasy, which now resembles that of the first phase, seems to have become sadistic once more. It appears as though in the phrase, 'My father is beating the child, he loves only me', the stress has been shifted back on to the first part after the second part has undergone repression. But only the *form* of this phantasy is sadistic; the satisfaction which is derived from it is masochistic. Its significance lies in the fact that it has taken over the libidinal cathexis of the repressed portion and at the same time the sense of guilt which is attached to the content of that portion. All of the many unspecified children who are being beaten by the teacher are, after all, nothing more than substitutes for the child itself.

We find here for the first time, too, something like a constancy of sex in the persons who play a part in the phantasy. The children who are being beaten are almost invariably boys, in the phantasies of boys just as much as in those of girls. This characteristic is naturally not to be explained by any rivalry between the sexes, as otherwise of course in the phantasies of boys it would be girls who would be being beaten; and it has nothing to do with the sex of the child who was hated in the first phase. But it points to a complication in the case of girls. When they turn away from their incestuous love for their father, with its genital significance, they easily abandon their feminine role. They spur their 'masculinity complex' (Van Ophuijsen, 1917) into activity, and from that time forward only want to be boys. For that reason the whipping-boys who represent them are boys too. In both the cases of day-dreaming - one of which almost rose to the level of a work of art - the heroes were always young men; indeed women used not to come into these creations at all, and only made their first appearance after many years, and then in minor parts.

V

I hope I have brought forward my analytic observations in sufficient detail, and I should only like to add that the six cases I have mentioned so often do not exhaust my material. Like other analysts, I have at my disposal a far larger number of cases which have been investigated less thoroughly. These observations can be made use of along various lines: for elucidating the genesis of the perversions in general and of masochism in particular, and for estimating the part played by difference of sex in the dynamics of neurosis.

The most obvious result of such a discussion is its application to the origin of the perversions. The view which brought into the foreground in this connection the constitutional reinforcement or premature growth of a single sexual component is not shaken, indeed; but it is seen not to comprise the whole truth. The perversion is no longer an isolated fact in the child's sexual life, but falls into its place among the typical, not to say normal, processes of development which are familiar to us. It is brought into relation with the child's incestuous love-object, with its Oedipus complex. It first comes into prominence in the sphere of this complex, and after the complex has broken down it remains over, often quite by itself, the inheritor of the charge of libido from that complex and weighed down by the sense of guilt that was attached to it. The abnormal sexual constitution, finally, has shown its strength by forcing the Oedipus complex into a particular direction, and by compelling it to leave an unusual residue behind.

A perversion in childhood, as is well known, may become the basis for the construction of a perversion having a similar sense and persisting throughout life, one which consumes the subject's whole sexual life. On the other hand the perversion may be broken off and remain in the background of a normal sexual development, from which, however, it continues to withdraw a certain amount of energy. The first of these alternatives was already known before the days of analysis. Analytic investigation, however, of such fully-developed cases almost bridges the gulf between the two. For we find often enough with these perverts that they too made an attempt at developing normal sexual activity, usually at the age of puberty; but their attempt had not enough force in it and was abandoned in the face of the first obstacles which inevitably arise, where upon they fell back upon their infantile fixation once and for all.

It would naturally be important to know whether the origin of infantile perversions from the Oedipus complex can be asserted as a general principle. While this cannot be decided without further investigation, it does not seem impossible. When we recall the anamneses which have been obtained in adult cases of perversion we cannot fail to notice that the decisive impression, the 'first experience', of all these perverts, fetishists, etc., is scarcely ever referred back to a time earlier than the sixth year. At this time, however, the dominance of the Oedipus complex is already over; the experience which is recalled, and which has been effective in such a puzzling way, may very well have represented the legacy of that complex. The connections between the experience and the complex which is by this time repressed are bound to remain obscure so long as analysis has not thrown any light on the time before the first 'pathogenic' impression. So it may be imagined how little value is to be attached, for instance, to an assertion that a case of homosexuality is congenital, when the ground given for this belief is that ever since his eighth or sixth year the person in question has felt inclinations only towards his own sex.

If, however, the derivation of perversions from the Oedipus complex can be generally established, our estimate of its importance will have gained added strength. For in our opinion the Oedipus complex is the actual nucleus of neuroses, and the infantile sexuality which culminates in this complex is the true determinant of neuroses. What remains of the complex in the unconscious represents the disposition to the later development of neuroses in the adult. In this way the beating-phantasy and other analogous perverse fixations would also only be precipitates of the Oedipus complex, scars, so to say, left behind after the process has ended, just as the notorious 'sense of inferiority' corresponds to a narcissistic scar of the same sort. In taking this view of the matter I must express my unreserved agreement with Marcinowski (1918), who has recently put it forward most happily. As is well known, this neurotic delusion of inferiority is only a partial one, and is completely compatible with the existence of a self-overvaluation derived from other sources. The origin of the Oedipus complex itself, and the destiny which compels man, probably alone among all animals, to begin his sexual life twice over, first like all other creatures in his early childhood, and then after a long interruption once more at the age of puberty - all the problems that are connected with man's 'archaic heritage' - have been discussed by me elsewhere, and I have no intention of going into them in this place.

Little light is thrown upon the genesis of masochism by our discussion of the beating-phantasy. To begin with, there seems to be a confirmation of the view that masochism is not the manifestation of a primary instinct, but originates from sadism which has been turned round upon the self - that is to say, by means of regression from an object to the ego.¹ Instincts with a passive aim must be taken for granted as existing, especially among women. But passivity is not the whole of masochism. The characteristic of unpleasure belongs to it as well, - a bewildering accompaniment to the satisfaction of an instinct. The transformation of sadism into masochism appears to be due to the influence of the sense of guilt which takes part in the act of repression. Thus repression is operative here in three ways: it renders the consequences of the genital organization unconscious, it compels that organization itself to regress to the earlier sadistic-anal stage, and it transforms the sadism of this stage into masochism, which is passive and again in a certain sense narcissistic. The second of these three effects is made possible by the weakness of the genital organization, which must be presupposed in these cases. The third becomes necessary because the sense of guilt takes as much objection to sadism as to incestuous object-choice genitally conceived. Again, the analyses do not tell us the origin of the sense of guilt itself. It seems to be brought along by the new phase upon which the child is entering, and, if it afterwards persists, it seems to correspond to a scar-like formation which is similar to the sense of inferiority. According to our present orientation in the structure of the ego, which is as yet uncertain, we should assign it to the agency in the mind which sets itself up as a critical conscience over against the rest of the ego, which produces Silberer's functional phenomenon in dreams, and which cuts itself loose from the ego in delusions of being watched.

¹ Cf. *Instincts and their Vicissitudes* (1915c).

We may note too in passing that the analysis of the infantile perversion dealt with here is also of help in solving an old riddle - one which, it is true, has always troubled those who have not accepted psycho-analysis more than analysts themselves. Yet quite recently even Bleuler regarded it as a remarkable and inexplicable fact that neurotics make masturbation the central point of their sense of guilt. We have long assumed that this sense of guilt relates to the masturbation of early childhood and not to that of puberty, and that in the main it is to be connected not with the act of masturbation but with the phantasy which, although unconscious, lies at its root - that is to say, with the Oedipus complex.

As regards the third and apparently sadistic phase of the beating-phantasy, I have already discussed the significance that it gains as the vehicle of the excitation impelling towards masturbation; and I have shown how it arouses activities of the imagination which on the one hand continue the phantasy along the same line, and on the other hand neutralize it through compensation. Nevertheless the second phase, the unconscious and masochistic one, in which the child itself is being beaten by its father, is incomparably the more important. This is not only because it continues to operate through the agency of the phase that takes its place; we can also detect effects upon the character, which are directly derived from its unconscious form. People who harbour phantasies of this kind develop a special sensitiveness and irritability towards anyone whom they can include in the class of fathers. They are easily offended by a person of this kind, and in that way (to their own sorrow and cost) bring about the realization of the imagined situation of being beaten by their father. I should not be surprised if it were one day possible to prove that the same phantasy is the basis of the delusional litigiousness of paranoia.

VI

It would have been quite impossible to give a clear survey of infantile beating-phantasies if I had not limited it, except in one or two connections, to the state of things in females. I will briefly recapitulate my conclusions. The little girl's beating phantasy passes through three phases, of which the first and third are consciously remembered, the middle one remaining unconscious. The two conscious phases appear to be sadistic, whereas the middle and unconscious one is undoubtedly of a masochistic nature; its content consists in the child's being beaten by her father, and it carries with it the libidinal charge and the sense of guilt. In the first and third phantasies the child who is being beaten is always someone other than the subject; in the middle phase it is always the child herself; in the third phase it is almost invariably only boys who are being beaten. The person who does the beating is from the first her father, replaced later on by a substitute taken from the class of fathers. The unconscious phantasy of the middle phase had primarily a genital significance and developed by means of repression and regression out of an incestuous wish to be loved by the father. Another fact, though its connection with the rest does not appear to be close, is that between the second and third phases the girls change their sex, for in the phantasies of the latter phase they turn into boys.

I have not been able to get so far in my knowledge of beating-phantasies in boys, perhaps because my material was unfavourable. I naturally expected to find a complete analogy between the state of things in the case of boys and in that of girls, the mother taking the father's place in the phantasy. This expectation seemed to be fulfilled; for the content of the boy's phantasy which was taken to be the corresponding one was actually his being beaten by his mother (or later on by a substitute for her). But this phantasy, in which the boy's own self was retained as the person who was being beaten, differed from the second phase in girls in that it was able to become conscious. If on this account, however, we attempt to draw a parallel between it and the *third* phase of the girl's phantasy, a new difference is found, for the figure of the boy himself is not replaced by a number of unknown, and unspecified children, least of all by a number of girls. Therefore the expectation of there being a complete parallel was mistaken.

My male cases with an infantile beating-phantasy comprised only a few who did not exhibit some other gross injury to their sexual activities; again they included a fairly large number of persons who would have to be described as true masochists in the sense of being sexual perverts. They were either people who obtained their sexual satisfaction exclusively from masturbation accompanied by masochistic phantasies; or they were people who had succeeded in combining masochism with their genital activity in such a way that, along with masochistic performances and under similar conditions, they were able to bring about erection and emission or to carry out normal intercourse. In addition to this there was the rarer case in which a masochist is interfered with in his perverse activities by the appearance of obsessional ideas of unbearable intensity. Now perverts who can obtain satisfaction do not often have occasion to come for analysis. But as regards the three classes of masochists that have been mentioned there may be strong motives to induce them to go to an analyst. The masochist masturbator finds that he is absolutely impotent if after all he does attempt intercourse with a woman; and the man who has hitherto effected intercourse with the help of a masochistic idea or performance may suddenly make the discovery that the alliance which was so convenient for him has broken down, his genital organs no longer reacting to the masochistic stimulus. We are accustomed confidently to promise recovery to psychically impotent patients who come to us for treatment; but we ought to be more guarded in making this prognosis so long as the dynamics of the disturbance are unknown to us. It comes as a disagreeable surprise if the analysis reveals the cause of the 'merely psychical' impotence to be a typically masochistic attitude, perhaps deeply embedded since infancy.

As regards these masochistic men, however, a discovery is made at this point which warns us not to pursue the analogy between their case and that of women any further at present, but to judge each independently. For the fact emerges that in their masochistic phantasies, as well as in the performances they go through for their realization, they invariably transfer themselves into the part of a woman; that is to say, their masochistic attitude coincides with a *feminine* one. This can easily be demonstrated from details of the phantasies; but many patients are even aware of it themselves, and give expression to it as a subjective conviction. It makes no difference if in a fanciful embellishment of the masochistic scene they keep up the fiction that a mischievous boy, or page, or apprentice is going to be punished. On the other hand the persons who administer chastisement are always women, both in the phantasies and the performances. This is confusing enough; and the further question must be asked whether this feminine attitude already forms the basis of the masochistic element in the *infantile* beating-phantasy.¹

Let us therefore leave aside consideration of the state of things in cases of adult masochism, which it is so hard to clear up, and turn to the infantile beating-phantasy in the male sex. Analysis of the earliest years of childhood once more allows us to make a surprising discovery in this field. The phantasy which has as its content being beaten by the mother, and which is conscious or can become so, is not a primary one. It possesses a preceding stage which is invariably unconscious and has as its content: '*I am being beaten by my father*.' This preliminary stage, then, really corresponds to the second phase of the phantasy in the girl. The familiar and conscious phantasy: 'I am being beaten by my mother', takes the place of the third phase in the girl, in which, as has been mentioned already, unknown boys are the objects that are being beaten. I have not been able to demonstrate among boys a preliminary stage of a sadistic nature that could be set beside the first phase of the phantasy in girls, but I will not now express any final disbelief in its existence, for I can readily see the possibility of meeting with more complicated types.

In the male phantasy - as I shall call it briefly, and, I hope, without any risk of being misunderstood - the being beaten also stands for being loved (in a genital sense), though this has been debased to a lower level owing to regression. So the original form of the unconscious male phantasy was not the provisional one that we have hitherto given: 'I am being beaten by my father', but rather: '*I am loved by my father*'. The phantasy has been transformed by the processes with which we are familiar into the conscious phantasy: '*I am being beaten by my mother*'. The boy's beating-phantasy is therefore passive from the very beginning, and is derived from a feminine attitude towards his father. It corresponds with the Oedipus complex just as the female one (that of the girl) does; only the parallel relation which we expected to find between the two must be given up in favour of a common character of another kind. *In both cases the beating-phantasy has its origin in an incestuous attachment to the father.*

¹ [Footnote added 1924:] Further remarks on this subject will be found in 'The Economic Problem of Masochism' (1924c).

It will help to make matters clearer if at this point I enumerate the other similarities and differences between beating phantasies in the two sexes. In the case of the girl the unconscious masochistic phantasy starts from the normal Oedipus attitude; in that of the boy it starts from the inverted attitude, in which the father is taken as the object of love. In the case of the girl the phantasy has a preliminary stage (the first phase), in which the beating bears no special significance and is performed upon a person who is viewed with jealous hatred. Both of these features are absent in the case of the boy, but this particular difference is one which might be removed by more fortunate observation. In her transition to the conscious phantasy which takes the place of the unconscious one, the girl retains the figure of her father, and in that way keeps unchanged the sex of the person beating; but she changes the figure and sex of the person being beaten, so that eventually a man is beating male children. The boy, on the contrary, changes the figure and sex of the person beating, by putting his mother in the place of his father; but he retains his own figure, with the result that the person beating and the person being beaten are of opposite sexes. In the case of the girl what was originally a masochistic (passive) situation is transformed into a sadistic one by means of repression, and its sexual quality is almost effaced. In the case of the boy the situation remains masochistic, and shows a greater resemblance to the original phantasy with its genital significance, since there is a difference of sex between the person beating and the person being beaten. The boy evades his homosexuality by repressing and remodelling his unconscious phantasy: and the remarkable thing about his later conscious phantasy is that it has for its content a feminine attitude without a homosexual object-choice. By the same process, on the other hand, the girl escapes from the demands of the erotic side of her life altogether. She turns herself in phantasy into a man, without herself becoming active in a masculine way, and is no longer anything but a spectator of the event which takes the place of a sexual act.

We are justified in assuming that no great change is effected by the *repression* of the original unconscious phantasy. Whatever is repressed from consciousness or replaced in it by something else remains intact and potentially operative in the unconscious. The effect of *regression* to an earlier stage of the sexual organization is quite another matter. As regards this we are led to believe that the state of things changes in the unconscious as well. Thus in both sexes the masochistic phantasy of being beaten by the father, though not the passive phantasy of being loved by him, lives on in the unconscious after repression has taken place. There are, besides, plenty of indications that the repression has only very incompletely attained its object. The boy, who has tried to escape from a homosexual object-choice, and who has not changed his sex, nevertheless feels like a woman in his conscious phantasies, and endows the women who are beating him with masculine attributes and characteristics. The girl, who has even renounced her sex, and who has on the whole accomplished a more thoroughgoing work of repression, nevertheless does not become freed from her father; she does not venture to do the beating herself; and since she has herself become a boy, it is principally boys whom she causes to be beaten.

I am aware that the differences that I have here described between the two sexes in regard to the nature of the beating-phantasy have not been cleared up sufficiently. But I shall not attempt to unravel these complications by tracing out their dependence on other factors, as I do not consider that the material for observation is exhaustive. So far as it goes, however, I should like to make use of it as a test for two theories. These theories stand in opposition to each other, though both of them deal with the relation between repression and sexual character, and each, according to its own view, represents the relation as a very intimate one. I may say at once that I have always regarded both theories as incorrect and misleading.

The first of these theories is anonymous. It was brought to my notice many years ago by a colleague with whom I was at that time on friendly terms. The theory is so attractive on account of its bold simplicity that the only wonder is that it should not have found its way into the literature of the subject except in a few scattered allusions. It is based on the fact of the bisexual constitution of human beings, and asserts that the motive force of repression in each individual is a struggle between the two sexual characters. The dominant sex of the person, that which is the more strongly developed, has repressed the mental representation of the subordinated sex into the unconscious. Therefore the nucleus of the unconscious (that is to say, the repressed) is in each human being that side of him which belongs to the opposite sex. Such a theory as this can only have an intelligible meaning if we assume that a person's sex is to be determined by the formation of his genitals; for otherwise it would not be certain which is a person's stronger sex and we should run the risk of reaching from the results of our enquiry the very fact which has to serve as its point of departure. To put the theory briefly: with men, what is unconscious and repressed can be brought down to feminine instinctual impulses; and conversely with women.

The second theory is of more recent origin. It is in agreement with the first one in so far as it too represents the struggle between the two sexes as being the decisive cause of repression. In other respects it comes into conflict with the former theory; moreover, it looks for support to sociological rather than biological sources. According to this theory of the 'masculine protest', formulated by Alfred Adler, every individual makes efforts not to remain on the inferior 'feminine line' and struggles towards the 'masculine line', from which satisfaction can alone be derived. Adler makes the masculine protest responsible for the whole formation both of character and of neuroses. Unfortunately he makes so little distinction between the two processes, which certainly have to be kept separate, and sets altogether so little store in general by the fact of repression, that to attempt to apply the doctrine of the masculine protest to repression brings with it the risk of misunderstanding. In my opinion such an attempt could only lead us to infer that the masculine protest, the desire to break away from the feminine line, was in every case the motive force of repression. The repressing agency, therefore, would always be a masculine instinctual impulse, and the repressed would be a feminine one. But symptoms would also be the result of a feminine impulse, for we cannot discard the characteristic feature of symptoms - that they are substitutes for the repressed, substitutes that have made their way out in spite of repression.

Now let us take these two theories, which may be said to have in common a sexualization of the process of repression, and test them by applying them to the example of the beating phantasies which we have been studying. The original phantasy, 'I am being beaten by my father', corresponds, in the case of the boy, to a feminine attitude, and is therefore an expression of that part of his disposition which belongs to the opposite sex. If this part of him undergoes repression, the first theory seems shown to be correct; for this theory set it up as a rule that what belongs to the opposite sex is identical with the repressed. It scarcely answers to our expectations, it is true, when we find that the conscious phantasy, which arises after repression has been accomplished, nevertheless exhibits the feminine attitude once more, though this time directed towards the mother. But we will not go into such doubtful points, when the whole question can be so quickly decided. There can be no doubt that the original phantasy in the case of the girl, 'I am being beaten (i. e. I am loved) by my father', represents a feminine attitude, and corresponds to her dominant and manifest sex; according to the theory, therefore, it ought to escape repression, and there would be no need for its becoming unconscious. But as a matter of fact it does become unconscious, and is replaced by a conscious phantasy which disavows the girl's manifest sexual character. The theory is therefore useless as an explanation of beating-phantasies, and is contradicted by the facts. It might be objected that it is precisely in unmanly boys and unwomanly girls that these beating-phantasies appeared and went through these vicissitudes; or that it was a trait of femininity in the boy and of masculinity in the girl which must be made responsible for the production of a passive phantasy in the boy, and its repression in the girl. We should be inclined to agree with this view, but it would not be any the less impossible to defend the supposed relation between manifest sexual character and the choice of what is destined for repression. In the last resort we can only see that both in male and female individuals masculine as well as feminine instinctual impulses are found, and that each can equally well undergo repression and so become unconscious.

The theory of the masculine protest seems to maintain its ground very much better on being tested in regard to the beating-phantasies. In the case of both boys and girls the beating phantasy corresponds with a feminine attitude - one, that is, in which the individual is lingering on the 'feminine line' - and both sexes hasten to get free from this attitude by repressing the phantasy. Nevertheless, it seems to be only with the girl that the masculine protest is attended with complete success, and in that instance, indeed, an ideal example is to be found of the operation of the masculine protest. With the boy the result is not entirely satisfactory; the feminine line is not given up, and the boy is certainly not 'on top' in his conscious masochistic phantasy. It would therefore agree with the expectations derived from the theory if we were to recognize that this phantasy was a symptom which had come into existence through the failure of the masculine protest. It is a disturbing fact, to be sure, that the girl's phantasy, which owes its origin to the forces of repression, also has the value and meaning of a symptom. In this instance, where the masculine protest has completely achieved its object, surely the determining condition for the formation of a symptom must be absent.

Before we are led by this difficulty to a suspicion that the whole conception of the masculine protest is inadequate to meet the problem of neuroses and perversions, and that its application to them is unfruitful, we will for a moment leave the passive beating-phantasies and turn our attention to other instinctual manifestations of infantile sexual life - manifestations which have equally undergone repression. No one can doubt that there are also wishes and phantasies which keep to the masculine line from their very nature, and which are the expression of masculine instinctual impulses - sadistic tendencies, for instance, or a boy's lustful feelings towards his mother arising out of the normal Oedipus complex. It is no less certain that these impulses, too, are overtaken by repression. If the masculine protest is to be taken as having satisfactorily explained the repression of passive phantasies (which later become masochistic), then it becomes for that very reason totally inapplicable to the opposite case of active phantasies. That is to say, the doctrine of the masculine protest is altogether incompatible with the fact of repression. Unless we are prepared to throw away all that has been acquired in psychology since Breuer's first cathartic treatment and through its agency, we cannot expect that the principle of the masculine protest will acquire any significance in the elucidation of the neuroses and perversions.

The theory of psycho-analysis (a theory based on observation) holds firmly to the view that the motive forces of repression must not be sexualized. Man's archaic heritage forms the nucleus of the unconscious mind; and whatever part of that heritage has to be left behind in the advance to later phases of development, because it is unserviceable or incompatible with what is new and harmful to it, falls a victim to the process of repression. This selection is made more successfully with one group of instincts than with the other. In virtue of special circumstances which have often been pointed out already, the latter group, that of the sexual instincts, are able to defeat the intentions of repression, and to enforce their representation by substitutive formations of a disturbing kind. For this reason infantile sexuality, which is held under repression, acts as the chief motive force in the formation of symptoms; and the essential part of its content, the Oedipus complex, is the nuclear complex of neuroses. I hope that in this paper I have raised an expectation that the sexual aberrations of childhood, as well as those of mature life, are ramifications of the same complex.

INTRODUCTION TO *PSYCHO-ANALYSIS AND THE WAR NEUROSES*
(1919)

Intentionally left blank

INTRODUCTION TO PSYCHO-ANALYSIS AND THE WAR NEUROSES

This small book on the war neuroses - the opening volume of our *Internationale Psychoanalytische Bibliothek* - deals with a subject which until recently enjoyed the advantage of being in the greatest degree topical. When it came up for discussion at the Fifth Psycho-Analytical Congress, which was held in Budapest in September, 1918, official representatives from the highest quarters of the Central European Powers were present as observers at the papers and other proceedings. The hopeful result of this first contact was that the establishment of psycho-analytic Centres was promised, at which analytically trained physicians would have leisure and opportunity for studying the nature of these puzzling disorders and the therapeutic effect exercised on them by psycho-analysis. Before these proposals could be put into effect, the war came to an end, the state organizations collapsed and interest in the war neuroses gave place to other concerns. It is, however, a significant fact that, when war conditions ceased to operate, the greater number of the neurotic disturbances brought about by the war simultaneously vanished. The opportunity for a thorough investigation of these affections was thus unluckily lost - though, we must add, the early recurrence of such an opportunity is not a thing to be desired.

But this episode, though it is now closed, was not without an important influence on the spread of psycho-analysis. Medical men who had hitherto held back from any approach to psycho-analytic theories were brought into closer contact with them when, in the course of their duties as army doctors, they were obliged to deal with war neuroses. The reader will be able to gather from Ferenczi's paper with what hesitations and under what disguises these closer contacts were made. Some of the factors which psycho-analysis had recognized and described long before as being at work in peace-time neuroses - the psychogenic origin of the symptoms, the importance of *unconscious* instinctual impulses, the part played in dealing with mental conflicts by the primary gain from being ill ('the flight into illness') - were observed to be present equally in the war neuroses and were accepted almost universally. Simmel's studies show, too, what successes could be achieved by treating war neurotics by the method of catharsis, which, as we know, was the first step towards the psycho-analytic technique.

There is, however, no need to consider that these approaches to psycho-analysis imply any reconciliation or any appeasement of opposition. Suppose someone has hitherto rejected the whole of a complex of interdependent propositions, but now suddenly finds himself in a position to convince himself of the truth of one portion of the whole. It might be thought that he will begin to hesitate about his opposition in general and permit himself some degree of deferent expectation that the other portion, about which he has had no personal experience and can consequently form no judgement of his own, may also turn out to be true. This other portion of psycho-analytic theory, with which the study of the war neuroses did not come into contact, is to the effect that the motive forces which are expressed in the formation of symptoms are sexual and that neuroses arise from a conflict between the ego and the sexual instincts which it repudiates. ('Sexuality' in this context is to be understood in the extended sense in which it is used in psycho-analysis and is not to be confused with the narrower concept of 'genitality'.) Now it is quite true, as Ernest Jones remarks in his contribution to this volume, that this portion of the theory has not yet been proved to apply to the war neuroses. The work that might prove it has not yet been taken in hand. It may be that the war neuroses are altogether unsuitable material for the purpose. But the opponents of psycho-analysis, whose dislike of sexuality is evidently stronger than their logic, have been in a hurry to proclaim that the investigation of the war neuroses has finally disproved this portion of psycho-analytic theory. They have been guilty here of a slight confusion. If the investigation of the war neuroses (and a very superficial one at that) has *not shown* that the sexual theory of the neuroses is *correct*, that is something very different from its *showing* that that theory is *incorrect*. With the help of an impartial attitude and a little good will, it should not be hard to find the way to a further clarification of the subject.

The war neuroses, in so far as they are distinguished from the ordinary neuroses of peace-time by special characteristics, are to be regarded as traumatic neuroses whose occurrence has been made possible or has been promoted by a conflict in the ego. Abraham's paper affords good evidence for this conflict, which has also been recognized by the English and American writers quoted by Jones. The conflict is between the soldier's old peaceful ego and his new warlike one, and it becomes acute as soon as the peace-ego realizes what danger it runs of losing its life owing to the rashness of its newly formed, parasitic double. It would be equally true to say that the old ego is protecting itself from a mortal danger by taking flight into a traumatic neurosis or to say that it is defending itself against the new ego which it sees is threatening its life. Thus the precondition of the war neuroses, the soil that nourishes them, would seem to be a national army; there would be no possibility of their arising in an army of professional soldiers or mercenaries.

Apart from this, the war neuroses are only traumatic neuroses, which, as we know, occur in peace-time too after frightening experiences or severe accidents, without any reference to a conflict in the ego.

The theory of the sexual aetiology of the neuroses, or, as we prefer to say, the libido theory of the neuroses, was originally put forward only in relation to the transference neuroses of peace-time and is easy to demonstrate in their case by the use of the technique of analysis. But its application to the other disorders which we later grouped together as the narcissistic neuroses already met with difficulties. An ordinary dementia praecox, a paranoia or a melancholia are essentially quite unsuitable material for demonstrating the validity of the libido theory or for serving as a first introduction to an understanding of it; and it is for that reason that psychiatrists, who neglect the transference neuroses, are unable to come to terms with it. But the traumatic neuroses of peace-time have always been regarded as the most refractory material of all in this respect; so that the emergence of the war neuroses could not introduce any new factor into the situation that already existed.

It only became possible to extend the libido theory to the narcissistic neuroses after the concept of a 'narcissistic libido' had been put forward and applied - a concept, that is, of an amount of sexual energy attached to the ego itself and finding satisfaction in the ego just as satisfaction is usually found only in objects. This entirely legitimate development of the concept of sexuality promises to accomplish as much for the severer neuroses and for the psychoses as can be expected of a theory which is feeling its way forwards on an empirical basis. The traumatic neuroses of peace will also fit into the scheme as soon as a successful outcome has been reached of our investigations into the relations which undoubtedly exist between fright, anxiety and narcissistic libido.

The traumatic neuroses and war neuroses may proclaim too loudly the effects of mortal danger and may be silent or speak only in muted tones of the effects of frustration in love. But, on the other hand, the ordinary transference neuroses of peace-time set no aetiological store by the factor of mortal danger which, in the former class of neuroses, plays so mighty a part. It is even held that the peace-time neuroses are promoted by indulgence, good living and inactivity - which would afford an interesting contrast to the living-conditions under which the war neuroses develop. If they were to follow the example of their opponents, psycho-analysts, finding that their patients had fallen ill owing to frustration in love (owing to the claims of the libido being unsatisfied) would have to maintain that there can be no such things as danger-neuroses or that the disorders that appear after frightening experiences are not neuroses. They have, of course, no notion of maintaining any such thing. On the contrary, a convenient possibility occurs to them of bringing the two apparently divergent sets of facts together under a single hypothesis. In traumatic and war neuroses the human ego is defending itself from a danger which threatens it from without or which is embodied in a shape assumed by the ego itself. In the transference neuroses of peace the enemy from which the ego is defending itself is actually the libido, whose demands seem to it to be menacing. In both cases the ego is afraid of being damaged - in the latter case by the libido and in the former by external violence. It might, indeed, be said that in the case of the war neuroses, in contrast to the pure traumatic neuroses and in approximation to the transference neuroses, what is feared is nevertheless an internal enemy. The theoretical difficulties standing in the way of a unifying hypothesis of this kind do not seem insuperable: after all, we have a perfect right to describe repression, which lies at the basis of every neurosis, as a reaction to a trauma - as an elementary traumatic neurosis.

APPENDIX

MEMORANDUM ON THE ELECTRICAL TREATMENT OF WAR NEUROTICS

(1955 [1920])

There were plenty of patients even in peace-time who, after traumas (that is, after frightening and dangerous experiences such as railway accidents, etc.) exhibited severe disturbances in their mental life and in their nervous activity, without physicians having reached an agreed judgement on these states. Some supposed that with such patients it was a question of severe injuries to the nervous system, similar to the haemorrhages and inflammations occurring in non-traumatic illnesses. And when anatomical examination failed to establish such processes, they nevertheless maintained their belief that finer changes in the tissues were the cause of the symptoms observed. They therefore classed these traumatic cases among the organic diseases. Other physicians maintained from the first that these states could only be regarded as functional disturbances, and that the nervous system remained anatomically intact. But medical opinion had long found difficulty in explaining how such severe disturbances of function could occur without any gross injury to the organ.

The war that has recently ended produced and brought under observation an immense number of these traumatic cases. In the result, the controversy was decided in favour of the functional view. The great majority of physicians no longer believe that the so-called 'war neurotics' are ill as a result of tangible organic injuries to the nervous system, and the more clear-sighted among them have already decided, instead of using the indefinite description of a 'functional change', to introduce the unambiguous term 'mental change'.

Although the war neuroses manifested themselves for the most part as motor disturbances - tremors and paralyses - and although it was plausible to suppose that such a gross impact as that produced by the concussion due to the explosion of a shell near by or to being buried by a fall of earth would lead to gross mechanical effects, observations were nevertheless made which left no doubt as to the psychical nature of the causation of these so-called war neuroses. How could this be disputed when the same symptoms appeared behind the Front as well, far from the horrors of war, or immediately after a return from leave? The physicians were therefore led to regard war neurotics in a similar light to the nervous subjects of peace-time.

What is known as the psycho-analytic school of psychiatry, which was brought into being by me, had taught for the last twenty-five years that the neuroses of peace could be traced back to disturbances of emotional life. This explanation was now applied quite generally to war neurotics. We had further asserted that neurotic patients suffered from mental conflicts and that the wishes and inclinations which were expressed in the symptoms were unknown to the patients themselves - were, that is to say, unconscious. It was therefore easy to infer that the immediate cause of all war neuroses was an unconscious inclination in the soldier to withdraw from the demands, dangerous or outrageous to his feelings, made upon him by active service. Fear of losing his own life, opposition to the command to kill other people, rebellion against the ruthless suppression of his own personality by his superiors - these were the most important affective sources on which the inclination to escape from war was nourished.

A soldier in whom these affective motives were very powerful and clearly conscious would, if he was a healthy man, have been obliged to desert or pretend to be ill. Only the smallest proportion of war neurotics, however, were malingerers; the emotional impulses which rebelled in them against active service and drove them into illness were operative in them without becoming conscious to them. They remained unconscious because other motives, such as ambition, self-esteem, patriotism, the habit of obedience and the example of others, were to start with more powerful until, on some appropriate occasion, they were overwhelmed by the other, unconsciously operating motives.

This insight into the causation of the war neuroses led to a method of treatment which seemed to be well-grounded and also proved highly effective in the first instance. It seemed expedient to treat the neurotic as a malingerer and to disregard the psychological distinction between conscious and unconscious intentions, although he was known not to be a malingerer. Since his illness served the purpose of withdrawing him from an intolerable situation, the roots of the illness would clearly be undermined if it was made even more intolerable to him than active service. Just as he had fled from the war into illness, means were now adopted which compelled him to flee back from illness into health, that is to say, into fitness for active service. For this purpose painful electrical treatment was employed, and with success. Physicians are glossing over the facts in retrospect when they assert that the strength of this electrical current was the same as had always been employed in functional disorders. This would only have been effective in the mildest cases; nor did it fit in with the underlying argument that a war neurotic's illness had to be made painful so that the balance of his motives would be tipped in favour of recovery.

This painful form of treatment introduced in the German army for therapeutic purposes could no doubt also be employed in a more moderate fashion. If it was used in the Vienna Clinics, I am personally convinced that it was never intensified to a cruel pitch by the initiative of Professor Wagner-Jauregg. I cannot vouch for other physicians whom I did not know. The psychological education of medical men is in general decidedly deficient and more than one of them may have forgotten that the patient whom he was seeking to treat as a malingerer was, after all, not one.

This therapeutic procedure, however, bore a stigma from the very first. It did not aim at the patient's recovery, or not in the first instance; it aimed, above all, at restoring his fitness for service. Here Medicine was serving purposes foreign to its essence. The physician himself was under military command and had his own personal dangers to fear - loss of seniority or a charge of neglecting his duty - if he allowed himself to be led by considerations other than those prescribed for him. The insoluble conflict between the claims of humanity, which normally carry decisive weight for a physician, and the demands of a national war was bound to confuse his activity.

Moreover, the successes of treatment by a strong electric current, which were brilliant to begin with, turned out afterwards not to be lasting. A patient who, having been restored to health by it, was sent back to the Front, could repeat the business afresh and have a relapse, by means of which he at least gained time and escaped the danger which was at the moment the immediate one. If he was once more under fire his fear of the electric current receded, just as during the treatment his fear of active service had faded. In the course of the war years, too, a rapidly increasing fatigue in the popular spirit made itself felt more and more, and a growing dislike of fighting, so that the treatment I have described began to fail in its effects. In these circumstances some of the army doctors gave way to the inclination, characteristic of Germans, to carry through their intentions regardless of all else - which should never have happened. The strength of the current, as well as the severity of the rest of the treatment, were increased to an unbearable point in order to deprive war neurotics of the advantage they gained from their illness. The fact has never been contradicted that in German hospitals there were deaths at that time during treatment and suicides as a result of it. I am quite unable to say, however, whether the Vienna Clinics, too, passed through this phase of therapy.

I am in a position to bring forward conclusive evidence of the final break-down of the electrical treatment of the war neuroses. In 1918 Dr. Ernst Simmel, head of a hospital for war neuroses at Posen, published a pamphlet in which he reported the extraordinarily favourable results achieved in severe cases of war neurosis by the psychotherapeutic method introduced by me. As a result of this publication, the next Psycho-Analytical Congress, held in Budapest in September 1918, was attended by official delegates of the German, Austrian and Hungarian Army Command, who promised that Centres should be set up for the purely psychological treatment of war neuroses. This promise was made although the delegates can have been left in no doubt that with this considerate, laborious and tedious kind of treatment it was impossible to count on the quickest restoration of these patients to fitness for service. Preparations for the establishment of Centres of this kind were actually under way, when the revolution broke out and put an end to the war and to the influence of the administrative offices which had hitherto been all-powerful. But with the end of the war the war neurotics, too, disappeared - a final but impressive proof of the psychical causation of their illnesses.

Vienna, 23. 2. 20.

3674

THE 'UNCANNY'

I

It is only rarely that a psycho-analyst feels impelled to investigate the subject of aesthetics, even when aesthetics is understood to mean not merely the theory of beauty but the theory of the qualities of feeling. He works in other strata of mental life and has little to do with the subdued emotional impulses which, inhibited in their aims and dependent on a host of concurrent factors, usually furnish the material for the study of aesthetics. But it does occasionally happen that he has to interest himself in some particular province of that subject; and this province usually proves to be a rather remote one, and one which has been neglected in the specialist literature of aesthetics.

The subject of the 'uncanny' is a province of this kind. It is undoubtedly related to what is frightening - to what arouses dread and horror; equally certainly, too, the word is not always used in a clearly definable sense, so that it tends to coincide with what excites fear in general. Yet we may expect that a special core of feeling is present which justifies the use of a special conceptual term. One is curious to know what this common core is which allows us to distinguish as 'uncanny' certain things which lie within the field of what is frightening.

As good as nothing is to be found upon this subject in comprehensive treatises on aesthetics, which in general prefer to concern themselves with what is beautiful, attractive and sublime - that is, with feelings of a positive nature - and with the circumstances and the objects that call them forth, rather than with the opposite feelings of repulsion and distress. I know of only one attempt in medico-psychological literature, a fertile but not exhaustive paper by Jentsch (1906). But I must confess that I have not made a very thorough examination of the literature, especially the foreign literature, relating to this present modest contribution of mine, for reasons which, as may easily be guessed, lie in the times in which we live; so that my paper is presented to the reader without any claim to priority.

In his study of the 'uncanny' Jentsch quite rightly lays stress on the obstacle presented by the fact that people vary so very greatly in their sensitivity to this quality of feeling. The writer of the present contribution, indeed, must himself plead guilty to a special obtuseness in the matter, where extreme delicacy of perception would be more in place. It is long since he has experienced or heard of anything which has given him an uncanny impression, and he must start by translating himself into that state of feeling, by awakening in himself the possibility of experiencing it. Still, such difficulties make themselves powerfully felt in many other branches of aesthetics; we need not on that account despair of finding instances in which the quality in question will be unhesitatingly recognized by most people.

Two courses are open to us at the outset. Either we can find out what meaning has come to be attached to the word 'uncanny' in the course of its history; or we can collect all those properties of persons, things, sense-impressions, experiences and situations which arouse in us the feeling of uncanniness, and then infer the unknown nature of the uncanny from what all these examples have in common. I will say at once that both courses lead to the same result: the uncanny is that class of the frightening which leads back to what is known of old and long familiar. How this is possible, in what circumstances the familiar can become uncanny and frightening, I shall show in what follows. Let me also add that my investigation was actually begun by collecting a number of individual cases, and was only later confirmed by an examination of linguistic usage. In this discussion, however, I shall follow the reverse course.

The German word '*unheimlich*' is obviously the opposite of '*heimlich*' ['homely'], '*heimisch*' ['native'] - the opposite of what is familiar; and we are tempted to conclude that what is 'uncanny' is frightening precisely because it is *not* known and familiar. Naturally not everything that is new and unfamiliar is frightening, however; the relation is not capable of inversion. We can only say that what is novel can easily become frightening and uncanny; some new things are frightening but not by any means all. Something has to be added to what is novel and unfamiliar in order to make it uncanny.

On the whole, Jentsch did not get beyond this relation of the uncanny to the novel and unfamiliar. He ascribes the essential factor in the production of the feeling of uncanniness to intellectual uncertainty; so that the uncanny would always, as it were, be something one does not know one's way about in. The better orientated in his environment a person is, the less readily will he get the impression of something uncanny in regard to the objects and events in it.

It is not difficult to see that this definition is incomplete, and we will therefore try to proceed beyond the equation 'uncanny' = 'unfamiliar'. We will first turn to other languages. But the dictionaries that we consult tell us nothing new, perhaps only because we ourselves speak a language that is foreign. Indeed, we get an impression that many languages are without a word for this particular shade of what is frightening.

I should like to express my indebtedness to Dr. Theodor Reik for the following excerpts:-

LATIN: (K. E. Georges, *Deutschlateinisches Wörterbuch*, 1898). An uncanny place: *locus suspectus*; at an uncanny time of night: *intempesta nocte*.

GREEK: (Rost's and Schenkl's Lexikons). *ξένος* (i. e. strange, foreign).

ENGLISH: (from the dictionaries of Lucas, Bellows, Flügel and Muret-Sanders). Uncomfortable, uneasy, gloomy, dismal, uncanny, ghastly; (of a house) haunted; (of a man) a repulsive fellow.

FRENCH: (Sachs-Villatte). *Inquiétant, sinistre, lugubre, mal à son aise*.

SPANISH: (Tollhausen, 1889). *Sospechoso, de mal aguero, lúgubre, siniestro*.

The Italian and Portuguese languages seem to content themselves with words which we should describe as circumlocutions. In Arabic and Hebrew 'uncanny' means the same as 'daemonic', 'gruesome'.

Let us therefore return to the German language. In Daniel Sanders's *Wörterbuch der Deutschen Sprache* (1860, 1, 729), the following entry, which I here reproduce in full, is to be found under the word '*heimlich*'. I have laid stress on one or two passages by italicizing them.

Heimlich, adj., subst. *Heimlichkeit* (pl. *Heimlichkeiten*): I. Also *heimelich*, *heimelig*, belonging to the house, not strange, familiar, tame, intimate, friendly, etc.

(a) (Obsolete) belonging to the house or the family, or regarded as so belonging (cf. Latin *familiaris*, familiar): *Die Heimlichen*, the members of the household; *Der heimliche Rat* (Gen. xli, 45; 2 Sam. xxiii. 23; 1 Chron. xii. 25; Wisd. viii. 4), now more usually *Geheimer Rat* [Privy Councillor].

(b) Of animals: tame, companionable to man. As opposed to wild, e. g. 'Animals which are neither wild nor *heimlich*', etc. 'Wild animals . . . that are trained to be *heimlich* and accustomed to men.' 'If these young creatures are brought up from early days among men they become quite *heimlich*, friendly' etc. - So also: 'It (the lamb) is so *heimlich* and eats out of my hand.' 'Nevertheless, the stork is a beautiful, *heimelich* bird.'

(c) Intimate, friendly comfortable; the enjoyment of quiet content, etc., arousing a sense of agreeable restfulness and security as in one within the four walls of his house. 'Is it still *heimlich* to you in your country where strangers are felling your woods?' 'She did not feel too *heimlich* with him.' 'Along a high, *heimlich*, shady path . . ., beside a purling, gushing and babbling woodland brook.' 'To destroy the *Heimlichkeit* of the home,' 'I could not readily find another spot so intimate and *heimlich* as this.' 'We pictured it so comfortable, so nice, so cosy and *heimlich*.' 'In quiet *Heimlichkeit*, surrounded by close walls.' 'A careful housewife, who knows how to make a pleasing *Heimlichkeit* (*Häuslichkeit*) out of the smallest means.' 'The man who till recently had been so strange to him now seemed to him all the more *heimlich*.' 'The protestant land-owners do not feel . . . *heimlich* among their catholic inferiors.' 'When it grows *heimlich* and still, and the evening quiet alone watches over your cell.' 'Quiet, lovely and *heimlich*, no place more fitted for their rest.' 'He did not feel at all *heimlich* about it.' - Also, 'The place was so peaceful, so lonely, so shadily-*heimlich*.' 'The in- and outflowing waves of the current, dreamy and lullaby-*heimlich*.' Cf. in especial *Unheimlich*. Among Swabian Swiss authors in especial, often as a trisyllable: 'How *heimelich* it seemed to Ivo again of an evening, when he was at home.' 'It was so *heimelig* in the house.' 'The warm room and the *heimelig* afternoon.' 'When a man feels in his heart that he is so small and the Lord so great - that is what is truly *heimelig*.' 'Little by little they grew at ease and *heimelig* among themselves.' 'Friendly *Heimeligkeit*.' 'I shall be nowhere more *heimelich* than I am here.' 'That which comes from afar . . . assuredly does not live quite *heimelig* (*heimatlich*, *freundnachbarlich*) among the people.' 'The cottage where he had once sat so often among his own people, so *heimelig*, so happy.' 'The sentinel's horn sounds so *heimelig* from the tower, and his voice invites so hospitably.' 'You go to sleep there so soft and warm, so wonderfully *heim'lig*.' - *This form of the word deserves to become general in order to protect this perfectly good sense of the word from becoming obsolete through an easy confusion with II. Cf.: "The Zecks are all 'heimlich'." (in sense II) "'Heimlich'? . . . What do you understand by 'heimlich'?" "Well, . . . they are like a buried spring or a dried-up pond. One cannot walk over it without always having the feeling that water might come up there again." "Oh, we call it 'unheimlich'; you call it 'heimlich'. Well, what makes you think that there is something secret and untrustworthy about this family?" (Gutzkow).*

(d) Especially in Silesia: gay, cheerful; also of the weather.

II. Concealed, kept from sight, so that others do not get to know of or about it, withheld from others. To do something *heimlich*, i.e. behind someone's back; to steal away *heimlich*; *heimlich* meetings and appointments; to look on with *heimlich* pleasure at someone's discomfiture; to sigh or weep *heimlich*; to behave *heimlich*, as though there was something to conceal; *heimlich* love-affair, love, sin; *heimlich* places (which good manners oblige us to conceal) (1 Sam. v. 6). 'The *heimlich* chamber' (privy) (2 Kings x. 27.). Also, 'the *heimlich* chair'. 'To throw into pits or *Heimlichkeiten*'. - 'Led the steeds *heimlich* before Laomedon.' - 'As secretive, *heimlich*, deceitful and malicious towards cruel masters . . . as frank, open, sympathetic and helpful towards a friend in misfortune.' 'You have still to learn what is *heimlich* holiest to me.' 'The *heimlich* art' (magic). 'Where public ventilation has to stop, there *heimlich* machinations begin.' 'Freedom is the whispered watchword of *heimlich* conspirators and the loud battle-cry of professed revolutionaries.' 'A holy, *heimlich* effect.' 'I have roots that are most *heimlich*. I am grown in the deep earth.' 'My *heimlich* pranks.' 'If he is not given it openly and scrupulously he may seize it *heimlich* and unscrupulously.' 'He had achromatic telescopes constructed *heimlich* and secretly.' 'Henceforth I desire that there should be nothing *heimlich* any longer between us.' - To discover, disclose, betray someone's *Heimlichkeiten*; 'to concoct *Heimlichkeiten* behind my back'. 'In my time we studied *Heimlichkeit*' 'The hand of understanding can alone undo the powerless spell of the *Heimlichkeit* (of hidden gold).' 'Say, where is the place of concealment . . . in what place of hidden *Heimlichkeit*?' 'Bees, who make the lock of *Heimlichkeiten*' (i. e. sealing-wax). 'Learned in strange *Heimlichkeiten* (magic arts).

The 'Uncanny'

For compounds see above, Ic. Note especially the negative '*un-*': eerie, weird, arousing gruesome fear: 'Seeming quite *unheimlich* and ghostly to him.' 'The *unheimlich*, fearful hours of night.' 'I had already long since felt an *unheimlich*, even gruesome feeling.' 'Now I am beginning to have an *unheimlich* feeling.' . . . 'Feels an *unheimlich* horror.' '*Unheimlich* and motionless like a stone image.' 'The *unheimlich* mist called hill-fog.' 'These pale youths are *unheimlich* and are brewing heaven knows what mischief.' "*Unheimlich*" is the name for everything that ought to have remained . . . secret and hidden but has come to light' (Schelling). - 'To veil the divine, to surround it with a certain *Unheimlichkeit*.' - *Unheimlich* is not often used as opposite to meaning II (above).

What interests us most in this long extract is to find that among its different shades of meaning the word '*heimlich*' exhibits one which is identical with its opposite, '*unheimlich*'. What is *heimlich* thus comes to be *unheimlich*. (Cf. the quotation from Gutzkow: 'We call it "*unheimlich*"; you call it "*heimlich*".') In general we are reminded that the word '*heimlich*' is not unambiguous, but belongs to two sets of ideas, which, without being contradictory, are yet very different: on the one hand it means what is familiar and agreeable, and on the other, what is concealed and kept out of sight. '*Unheimlich*' is customarily used, we are told, as the contrary only of the first signification of *heimlich*', and not of the second. Sanders tells us nothing concerning a possible genetic connection between these two meanings of *heimlich*. On the other hand, we notice that Schelling says something which throws quite a new light on the concept of the *Unheimlich*, for which we were certainly not prepared. According to him, everything is *unheimlich* that ought to have remained secret and hidden but has come to light.

Some of the doubts that have thus arisen are removed if we consult Grimm's dictionary. (1877, 4, Part 2, 873 ff.)

We read:

Heimlich; adj. and adv. *vernaculus, occultus*; MHG. heimelîch, heimlîch.

(P. 874.) In a slightly different sense: 'I feel *heimlich*, well, free from fear.' . . .

(b) *Heimlich* is also used of a place free from ghostly influences . . . familiar, friendly, intimate.

(P. 875: β) Familiar, amicable, unreserved.

4. From the idea of 'homelike', 'belonging to the house', the further idea is developed of something withdrawn from the eyes of strangers, something concealed, secret; and this idea is expanded in many ways . . .

(P. 876.) 'On the left bank of the lake there lies a meadow *heimlich* in the wood.' (Schiller, *Wilhelm Tell*, I. 4.) . . . Poetic licence, rarely so used in modern speech . . . *Heimlich* is used in conjunction with a verb expressing the act of concealing: 'In the secret of his tabernacle he shall hide me *heimlich*.' (Ps. xxvii.

5.) . . . *Heimlich* parts of the human body, *pudenda* . . . 'the men that died not were smitten on their *heimlich* parts.' (1 Samuel v. 12.) . . .

(c) Officials who give important advice which has to be kept secret in matters of state are called *heimlich* councillors; the adjective, according to modern usage, has been replaced by *geheim* [secret] . . . 'Pharaoh called Joseph's name "him to whom secrets are revealed"' (*heimlich* councillor). (Gen. xli. 45.)

(P. 878.) 6. *Heimlich*, as used of knowledge - mystic, allegorical: a *heimlich* meaning, *mysticus, divinus, occultus, figuratus*.

(P. 878.) *Heimlich* in a different sense, as withdrawn from knowledge, unconscious . . . *Heimlich* also has the meaning of that which is obscure, inaccessible to knowledge . . . 'Do you not see? They do not trust us; they fear the *heimlich* face of the Duke of Friedland.' (Schiller, *Wallensteins Lager*, Scene 2.)

9. The notion of something hidden and dangerous, which is expressed in the last paragraph, is still further developed, so that '*heimlich*' comes to have the meaning usually ascribed to '*unheimlich*'. Thus: 'At times I feel like a man who walks in the night and believes in ghosts; every corner is *heimlich* and full of terrors for him'. (Klinger, *Theater*, 3. 298.)

Thus *heimlich* is a word the meaning of which develops in the direction of ambivalence, until it finally coincides with its opposite, *unheimlich*. *Unheimlich* is in some way or other a sub-species of *heimlich*. Let us bear this discovery in mind, though we cannot yet rightly understand it, alongside of Schelling's definition of the *Unheimlich*. If we go on to examine individual instances of uncanniness, these hints will become intelligible to us.

II

When we proceed to review the things, persons, impressions, events and situations which are able to arouse in us a feeling of the uncanny in a particularly forcible and definite form, the first requirement is obviously to select a suitable example to start on. Jentsch has taken as a very good instance 'doubts whether an apparently animate being is really alive; or conversely, whether a lifeless object might not be in fact animate'; and he refers in this connection to the impression made by wax-work figures, ingeniously constructed dolls and automata. To these he adds the uncanny effect of epileptic fits, and of manifestations of insanity, because these excite in the spectator the impression of automatic, mechanical processes at work behind the ordinary appearance of mental activity. Without entirely accepting this author's view, we will take it as a starting-point for our own investigation because in what follows he reminds us of a writer who has succeeded in producing uncanny effects better than anyone else.

Jentsch writes: 'In telling a story, one of the most successful devices for easily creating uncanny effects is to leave the reader in uncertainty whether a particular figure in the story is a human being or an automaton, and to do it in such a way that his attention is not focused directly upon his uncertainty, so that he may not be led to go into the matter and clear it up immediately. That, as we have said, would quickly dissipate the peculiar emotional effect of the thing. E. T. A. Hoffmann has repeatedly employed this psychological artifice with success in his fantastic narratives.'

This observation, undoubtedly a correct one, refers primarily to the story of 'The Sand-Man' in Hoffmann's *Nachtstücken*,¹ which contains the original of Olympia, the doll that appears in the first act of Offenbach's opera, *Tales of Hoffman*. But I cannot think - and I hope most readers of the story will agree with me - that the theme of the doll Olympia, who is to all appearances a living being, is by any means the only, or indeed the most important, element that must be held responsible for the quite unparalleled atmosphere of uncanniness evoked by the story. Nor is this atmosphere heightened by the fact that the author himself treats the episode of Olympia with a faint touch of satire and uses it to poke fun at the young man's idealization of his mistress. The main theme of the story is, on the contrary, something different, something which gives it its name, and which is always re-introduced at critical moments: it is the theme of the 'Sand-Man' who tears out children's eyes.

This fantastic tale opens with the childhood recollections of the student Nathaniel. In spite of his present happiness, he cannot banish the memories associated with the mysterious and terrifying death of his beloved father. On certain evenings his mother used to send the children to bed early, warning them that 'the Sand-Man was coming'; and, sure enough, Nathaniel would not fail to hear the heavy tread of a visitor, with whom his father would then be occupied for the evening. When questioned about the Sand-Man, his mother, it is true, denied that such a person existed except as a figure of speech; but his nurse could give him more definite information: 'He's a wicked man who comes when children won't go to bed, and throws handfuls of sand in their eyes so that they jump out of their heads all bleeding. Then he puts the eyes in a sack and carries them off to the half-moon to feed his children. They sit up there in their nest, and their beaks are hooked like owls' beaks, and they use them to peck up naughty boys' and girls' eyes with.'

¹ Hoffmann's *Sämtliche Werke*, Grisebach Edition, 3.

Although little Nathaniel was sensible and old enough not to credit the figure of the Sand-Man with such gruesome attributes, yet the dread of him became fixed in his heart. He determined to find out what the Sand-Man looked like; and one evening, when the Sand-Man was expected again, he hid in his father's study. He recognized the visitor as the lawyer Coppelius, a repulsive person whom the children were frightened of when he occasionally came to a meal; and he now identified this Coppelius with the dreaded Sand-Man. As regards the rest of the scene, Hoffmann already leaves us in doubt whether what we are witnessing is the first delirium of the panic-stricken boy, or a succession of events which are to be regarded in the story as being real. His father and the guest are at work at a brazier with glowing flames. The little eavesdropper hears Coppelius call out: 'Eyes here! Eyes here!' and betrays himself by screaming aloud. Coppelius seizes him and is on the point of dropping bits of red-hot coal from the fire into his eyes, and then of throwing them into the brazier, but his father begs him off and saves his eyes. After this the boy falls into a deep swoon; and a long illness brings his experience to an end. Those who decide in favour of the rationalistic interpretation of the Sand-Man will not fail to recognize in the child's phantasy the persisting influence of his nurse's story. The bits of sand that are to be thrown into the child's eyes turn into bits of red-hot coal from the flames; and in both cases they are intended to make his eyes jump out. In the course of another visit of the Sand-Man's, a year later, his father is killed in his study by an explosion. The lawyer Coppelius disappears from the place without leaving a trace behind.

Nathaniel, now a student, believes that he has recognized this phantom of horror from his childhood in an itinerant optician, an Italian called Giuseppe Coppola, who at his university town, offers him weather-glasses for sale. When Nathaniel refuses, the man goes on: 'Not weather-glasses? not weather-glasses? also got fine eyes, fine eyes!' The student's terror is allayed when he finds that the proffered eyes are only harmless spectacles, and he buys a pocket spy-glass from Coppola. With its aid he looks across into Professor Spalanzani's house opposite and there spies Spalanzani's beautiful, but strangely silent and motionless daughter, Olympia. He soon falls in love with her so violently that, because of her, he quite forgets the clever and sensible girl to whom he is betrothed. But Olympia is an automaton whose clock-work has been made by Spalanzani, and whose eyes have been put in by Coppola, the Sand-Man. The student surprises the two Masters quarrelling over their handiwork. The optician carries off the wooden eyeless doll; and the mechanician, Spalanzani, picks up Olympia's bleeding eyes from the ground and throws them at Nathaniel's breast, saying that Coppola had stolen them from the student. Nathaniel succumbs to a fresh attack of madness, and in his delirium his recollection of his father's death is mingled with this new experience. 'Hurry up! hurry up! ring of fire!' he cries. 'Spin about, ring of fire - Hurrah! Hurry up, wooden doll! lovely wooden doll, spin about -.' He then falls upon the professor, Olympia's 'father', and tries to strangle him.

Rallying from a long and serious illness, Nathaniel seems at last to have recovered. He intends to marry his betrothed, with whom he has become reconciled. One day he and she are walking through the city market-place, over which the high tower of the Town Hall throws its huge shadow. On the girl's suggestion, they climb the tower, leaving her brother, who is walking with them, down below. From the top, Clara's attention is drawn to a curious object moving along the street. Nathaniel looks at this thing through Coppola's spy-glass, which he finds in his pocket, and falls into a new attack of madness. Shouting 'Spin about, wooden doll!' he tries to throw the girl into the gulf below. Her brother, brought to her side by her cries, rescues her and hastens down with her to safety. On the tower above, the madman rushes round, shrieking 'Ring of fire, spin about!' - and we know the origin of the words. Among the people who begin to gather below there comes forward the figure of the lawyer Coppelius, who has suddenly returned. We may suppose that it was his approach, seen through the spy-glass, which threw Nathaniel into his fit of madness. As the onlookers prepare to go up and overpower the madman, Coppelius laughs and says: 'Wait a bit; he'll come down of himself.' Nathaniel suddenly stands still, catches sight of Coppelius, and with a wild shriek 'Yes! "Fine eyes - fine eyes!"' flings himself over the parapet. While he lies on the paving-stones with a shattered skull the Sand-Man vanishes in the throng.

This short summary leaves no doubt, I think, that the feeling of something uncanny is directly attached to the figure of the Sand-Man, that is, to the idea of being robbed of one's eyes, and that Jentsch's point of an intellectual uncertainty has nothing to do with the effect. Uncertainty whether an object is living or inanimate, which admittedly applied to the doll Olympia, is quite irrelevant in connection with this other, more striking instance of uncanniness. It is true that the writer creates a kind of uncertainty in us in the beginning by not letting us know, no doubt purposely, whether he is taking us into the real world or into a purely fantastic one of his own creation. He has, of course, a right to do either; and if he chooses to stage his action in a world peopled with spirits, demons and ghosts, as Shakespeare does in *Hamlet*, in *Macbeth* and, in a different sense, in *A Midsummer-Night's Dream*, we must bow to his decision and treat his setting as though it were real for as long as we put ourselves into his hands. But this uncertainty disappears in the course of Hoffmann's story, and we perceive that he intends to make us, too, look through the demon optician's spectacles or spy-glass - perhaps, indeed, that the author in his very own person once peered through such an instrument. For the conclusion of the story makes it quite clear that Coppola the optician really *is* the lawyer Coppelius ¹ and also, therefore, the Sand-Man.

There is no question therefore, of any intellectual uncertainty here: we know now that we are not supposed to be looking on at the products of a madman's imagination, behind which we, with the superiority of rational minds, are able to detect the sober truth; and yet this knowledge does not lessen the impression of uncanniness in the least degree. The theory of intellectual uncertainty is thus incapable of explaining that impression.

¹ Frau Dr. Rank has pointed out the association of the name with '*coppella*' = crucible, connecting it with the chemical operations that caused the father's death; and also with '*coppo*' = eye-socket.

We know from psycho-analytic experience, however, that the fear of damaging or losing one's eyes is a terrible one in children. Many adults retain their apprehensiveness in this respect, and no physical injury is so much dreaded by them as an injury to the eye. We are accustomed to say, too, that we will treasure a thing as the apple of our eye. A study of dreams, phantasies and myths has taught us that anxiety about one's eyes, the fear of going blind, is often enough a substitute for the dread of being castrated. The self-blinding of the mythical criminal, Oedipus, was simply a mitigated form of the punishment of castration - the only punishment that was adequate for him by the *lex talionis*. We may try on rationalistic grounds to deny that fears about the eye are derived from the fear of castration, and may argue that it is very natural that so precious an organ as the eye should be guarded by a proportionate dread. Indeed, we might go further and say that the fear of castration itself contains no other significance and no deeper secret than a justifiable dread of this rational kind. But this view does not account adequately for the substitutive relation between the eye and the male organ which is seen to exist in dreams and myths and phantasies; nor can it dispel the impression that the threat of being castrated in especial excites a peculiarly violent and obscure emotion, and that this emotion is what first gives the idea of losing other organs its intense colouring. All further doubts are removed when we learn the details of their 'castration complex' from the analysis of neurotic patients, and realize its immense importance in their mental life.

Moreover, I would not recommend any opponent of the psycho-analytic view to select this particular story of the Sand-Man with which to support his argument that anxiety about the eyes has nothing to do with the castration complex. For why does Hoffmann bring the anxiety about eyes into such intimate connection with the father's death? And why does the Sand-Man always appear as a disturber of love? He separates the unfortunate Nathaniel from his betrothed and from her brother, his best friend; he destroys the second object of his love, Olympia, the lovely doll; and he drives him into suicide at the moment when he has won back his Clara and is about to be happily united to her. Elements in the story like these, and many others, seem arbitrary and meaningless so long as we deny all connection between fears about the eye and castration; but they become intelligible as soon as we replace the Sand-Man by the dreaded father at whose hands castration is expected.¹

¹ In fact, Hoffman's imaginative treatment of his material has not made such wild confusion of its elements that we cannot reconstruct their original arrangement. In the story of Nathaniel's childhood, the figures of his father and Coppeliuss represent the two opposites into which the father-imago is split by his ambivalence; whereas the one threatens to blind him - that is, to castrate him -, the other, the 'good' father, intercedes for his sight. The part of the complex which is most strongly repressed, the death-wish against the 'bad' father, finds expression in the death of the 'good' father, and Coppeliuss is made answerable for it. This pair of fathers is represented later, in his student days, by Professor Spalanzani and Coppola the optician. The Professor is in himself a member of the father-series, and Coppola is recognized as identical with Coppeliuss the lawyer. Just as they used before to work together over the secret brazier, so now they have jointly created the doll Olympia; the Professor is even called the father of Olympia. This double occurrence of activity in common betrays them as divisions of the father-imago: both the mechanician and the optician were the father of Nathaniel (and of Olympia as well). In the frightening scene in childhood, Coppeliuss, after sparing Nathaniel's eyes, had screwed off his arms and legs as an experiment; that is, he had worked on him as a mechanician would on a doll. This singular feature, which seems quite outside the picture of the Sand-Man, introduces a new castration equivalent; but it also points to the inner identity of Coppeliuss with his later counterpart, Spalanzani the mechanician, and prepares us for the interpretation of Olympia. This automatic doll can be nothing else than a materialization of Nathaniel's feminine attitude towards his father in his infancy. Her fathers, Spalanzani and Coppola, are, after all, nothing but new editions, reincarnations of Nathaniel's pair of fathers. Spalanzani's otherwise incomprehensible statement that the optician has stolen Nathaniel's eyes (see above), so as to set them in the doll, now become significant as supplying evidence of the identity of Olympia and Nathaniel. Olympia is, as it were, a dissociated complex of Nathaniel's which confronts him as a person, and Nathaniel's enslavement to this complex is expressed in his senseless obsessive love for Olympia. We may with justice call love of this kind narcissistic, and we can understand why someone who has fallen victim to it should relinquish the real, external object of his love. The psychological truth of the situation in which the young man, fixated upon his father by his castration complex, becomes incapable of loving a woman, is amply proved by numerous analyses of patients whose story, though less fantastic, is hardly less tragic than that of the student Nathaniel.

Hoffmann was the child of an unhappy marriage. When he was three years old, his father left his small family, and was never united to them again. According to Grisebach, in his biographical introduction to Hoffmann's works, the writer's relation to his father was always a most sensitive subject with him.

We shall venture, therefore, to refer the uncanny effect of the Sand-Man to the anxiety belonging to the castration complex of childhood. But having reached the idea that we can make an infantile factor such as this responsible for feelings of uncanniness, we are encouraged to see whether we can apply it to other instances of the uncanny. We find in the story of the Sand-Man the other theme on which Jentsch lays stress, of a doll which appears to be alive. Jentsch believes that a particularly favourable condition for awakening uncanny feelings is created when there is intellectual uncertainty whether an object is alive or not, and when an inanimate object becomes too much like an animate one. Now, dolls are of course rather closely connected with childhood life. We remember that in their early games children do not distinguish at all sharply between living and inanimate objects, and that they are especially fond of treating their dolls like live people. In fact, I have occasionally heard a woman patient declare that even at the age of eight she had still been convinced that her dolls would be certain to come to life if she were to look at them in a particular, extremely concentrated, way. So that here, too, it is not difficult to discover a factor from childhood. But, curiously enough, while the Sand-Man story deals with the arousing of an early childhood fear, the idea of a 'living doll' excites no fear at all; children have no fear of their dolls coming to life, they may even desire it. The source of uncanny feelings would not, therefore, be an infantile fear in this case, but rather an infantile wish or even merely an infantile belief. There seems to be a contradiction here; but perhaps it is only a complication, which may be helpful to us later on.

Hoffmann is the unrivalled master of the uncanny in literature. His novel, *Die Elixire des Teufels*, contains a whole mass of themes to which one is tempted to ascribe the uncanny effect of the narrative; but it is too obscure and intricate a story for us to venture upon a summary of it. Towards the end of the book the reader is told the facts, hitherto concealed from him, from which the action springs; with the result, not that he is at last enlightened, but that he falls into a state of complete bewilderment. The author has piled up too much material of the same kind. In consequence one's grasp of the story as a whole suffers, though not the impression it makes. We must content ourselves with selecting those themes of uncanniness which are most prominent, and with seeing whether they too can fairly be traced back to infantile sources. These themes are all concerned with the phenomenon of the 'double', which appears in every shape and in every degree of development. Thus we have characters who are to be considered identical because they look alike. This relation is accentuated by mental processes leaping from one of these characters to another - by what we should call telepathy -, so that the one possesses knowledge, feelings and experience in common with the other. Or it is marked by the fact that the subject identifies himself with someone else, so that he is in doubt as to which his self is, or substitutes the extraneous self for his own. In other words, there is a doubling, dividing and interchanging of the self. And finally there is the constant recurrence of the same thing - the repetition of the same features or character-traits or vicissitudes, of the same crimes, or even the same names through several consecutive generations.

The theme of the 'double' has been very thoroughly treated by Otto Rank (1914). He has gone into the connections which the 'double' has with reflections in mirrors, with shadows, with guardian spirits, with the belief in the soul and with the fear of death; but he also lets in a flood of light on the surprising evolution of the idea. For the 'double' was originally an insurance against the destruction of the ego, an 'energetic denial of the power of death', as Rank says; and probably the 'immortal' soul was the first 'double' of the body. This invention of doubling as a preservation against extinction has its counterpart in the language of dreams, which is fond of representing castration by a doubling or multiplication of a genital symbol. The same desire led the Ancient Egyptians to develop the art of making images of the dead in lasting materials. Such ideas, however, have sprung from the soil of unbounded self-love, from the primary narcissism which dominates the mind of the child and of primitive man. But when this stage has been surmounted, the 'double' reverses its aspect. From having been an assurance of immortality, it becomes the uncanny harbinger of death.

The idea of the 'double' does not necessarily disappear with the passing of primary narcissism, for it can receive fresh meaning from the later stages of the ego's development. A special agency is slowly formed there, which is able to stand over against the rest of the ego, which has the function of observing and criticizing the self and of exercising a censorship within the mind, and which we become aware of as our 'conscience'. In the pathological case of delusions of being watched, this mental agency becomes isolated, dissociated from the ego, and discernible to the physician's eye. The fact that an agency of this kind exists, which is able to treat the rest of the ego like an object - the fact, that is, that man is capable of self-observation - renders it possible to invest the old idea of a 'double' with a new meaning and to ascribe a number of things to it - above all, those things which seem to self-criticism to belong to the old surmounted narcissism of earliest times.¹

¹ I believe that when poets complain that two souls dwell in the human breast, and when popular psychologists talk of the splitting of people's egos, what they are thinking of is this division (in the sphere of ego-psychology) between the critical agency and the rest of the ego, and not the antithesis discovered by psycho-analysis between the ego and what is unconscious and repressed. It is true that the distinction between these two antitheses is to some extent effaced by the circumstance that foremost among the things that are rejected by the criticism of the ego are derivatives of the repressed.

But it is not only this latter material, offensive as it is to the criticism of the ego, which may be incorporated in the idea of a double. There are also all the unfulfilled but possible futures to which we still like to cling in phantasy, all the strivings of the ego which adverse external circumstances have crushed, and all our suppressed acts of volition which nourish in us the illusion of Free Will.¹

But after having thus considered the *manifest* motivation of the figure of a 'double', we have to admit that none of this helps us to understand the extraordinarily strong feeling of something uncanny that pervades the conception; and our knowledge of pathological mental processes enables us to add that nothing in this more superficial material could account for the urge towards defence which has caused the ego to project that material outward as something foreign to itself. When all is said and done, the quality of uncanniness can only come from the fact of the 'double' being a creation dating back to a very early mental stage, long since surmounted - a stage, incidentally, at which it wore a more friendly aspect. The 'double' has become a thing of terror, just as, after the collapse of their religion, the gods turned into demons.²

The other forms of ego-disturbance exploited by Hoffmann can easily be estimated along the same lines as the theme of the 'double'. They are a harking-back to particular phases in the evolution of the self-regarding feeling, a regression to a time when the ego had not yet marked itself off sharply from the external world and from other people. I believe that these factors are partly responsible for the impression of uncanniness, although it is not easy to isolate and determine exactly their share of it.

¹ In Ewers's *Der Student von Prag*, which serves as the starting-point of Rank's study on the 'double', the hero has promised his beloved not to kill his antagonist in a duel. But on his way to the duelling-ground he meets his 'double', who has already killed his rival.

² Heine, *Die Götter im Exil*.

The factor of the repetition of the same thing will perhaps not appeal to everyone as a source of uncanny feeling. From what I have observed, this phenomenon does undoubtedly, subject to certain conditions and combined with certain circumstances, arouse an uncanny feeling, which, furthermore, recalls the sense of helplessness experienced in some dream states. As I was walking, one hot summer afternoon, through the deserted streets of a provincial town in Italy which was unknown to me, I found myself in a quarter of whose character I could not long remain in doubt. Nothing but painted women were to be seen at the windows of the small houses, and I hastened to leave the narrow street at the next turning. But after having wandered about for a time without enquiring my way, I suddenly found myself back in the same street, where my presence was now beginning to excite attention. I hurried away once more, only to arrive by another *détour* at the same place yet a third time. Now, however, a feeling overcame me which I can only describe as uncanny, and I was glad enough to find myself back at the piazza I had left a short while before, without any further voyages of discovery. Other situations which have in common with my adventure an unintended recurrence of the same situation, but which differ radically from it in other respects, also result in the same feeling of helplessness and of uncanniness. So, for instance, when, caught in a mist perhaps, one has lost one's way in a mountain forest, every attempt to find the marked or familiar path may bring one back again and again to one and the same spot, which one can identify by some particular landmark. Or one may wander about in a dark, strange room, looking for the door or the electric switch, and collide time after time with the same piece of furniture - though it is true that Mark Twain succeeded by wild exaggeration in turning this latter situation into something irresistibly comic.

If we take another class of things, it is easy to see that there, too, it is only this factor of involuntary repetition which surrounds what would otherwise be innocent enough with an uncanny atmosphere, and forces upon us the idea of something fateful and inescapable when otherwise we should have spoken only of 'chance'. For instance, we naturally attach no importance to the event when we hand in an overcoat and get a cloak room ticket with the number, let us say, 62; or when we find that our cabin on a ship bears that number. But the impression is altered if two such events, each in itself indifferent, happen close together - if we come across the number 62 several times in a single day, or if we begin to notice that everything which has a number - addresses, hotel rooms, compartments in railway trains - invariably has the same one, or at all events one which contains the same figures. We do feel this to be uncanny. And unless a man is utterly hardened and proof against the lure of superstition, he will be tempted to ascribe a secret meaning to this obstinate recurrence of a number; he will take it, perhaps, as an indication of the span of life allotted to him. Or suppose one is engaged in reading the works of the famous physiologist, Hering, and within the space of a few days receives two letters from two different countries, each from a person called Hering, though one has never before had any dealings with anyone of that name. Not long ago an ingenious scientist (Kammerer, 1919) attempted to reduce coincidences of this kind to certain laws, and so deprive them of their uncanny effect. I will not venture to decide whether he has succeeded or not.

How exactly we can trace back to infantile psychology the uncanny effect of such similar recurrences is a question I can only lightly touch on in these pages; and I must refer the reader instead to another work, already completed, in which this has been gone into in detail, but in a different connection. For it is possible to recognize the dominance in the unconscious mind of a 'compulsion to repeat' proceeding from the instinctual impulses and probably inherent in the very nature of the instincts - a compulsion powerful enough to overrule the pleasure principle, lending to certain aspects of the mind their daemonic character, and still very clearly expressed in the impulses of small children; a compulsion, too, which is responsible for a part of the course taken by the analyses of neurotic patients. All these considerations prepare us for the discovery that whatever reminds us of this inner 'compulsion to repeat' is perceived as uncanny.

Now, however, it is time to turn from these aspects of the matter, which are in any case difficult to judge, and look for some undeniable instances of the uncanny, in the hope that an analysis of them will decide whether our hypothesis is a valid one.

In the story of 'The Ring of Polycrates', the King of Egypt turns away in horror from his host, Polycrates, because he sees that his friend's every wish is at once fulfilled, his every care promptly removed by kindly fate. His host has become 'uncanny' to him. His own explanation, that the too fortunate man has to fear the envy of the gods, seems obscure to us; its meaning is veiled in mythological language. We will therefore turn to another example in a less grandiose setting. In the case history of an obsessional neurotic,¹ I have described how the patient once stayed in a hydropathic establishment and benefited greatly by it. He had the good sense, however, to attribute his improvement not to the therapeutic properties of the water, but to the situation of his room, which immediately adjoined that of a very accommodating nurse. So on his second visit to the establishment he asked for the same room, but was told that it was already occupied by an old gentleman, whereupon he gave vent to his annoyance in the words: 'I wish he may be struck dead for it.' A fortnight later the old gentleman really did have a stroke. My patient thought this an 'uncanny' experience. The impression of uncanniness would have been stronger still if less time had elapsed between his words and the untoward event, or if he had been able to report innumerable similar coincidences. As a matter of fact, he had no difficulty in producing coincidences of this sort; but then not only he but every obsessional neurotic I have observed has been able to relate analogous experiences. They are never surprised at their invariably running up against someone they have just been thinking of, perhaps for the first time for a long while. If they say one day 'I haven't had any news of so-and-so for a long time', they will be sure to get a letter from him the next morning, and an accident or a death will rarely take place without having passed through their mind a little while before. They are in the habit of referring to this state of affairs in the most modest manner, saying that they have 'presentiments' which 'usually' come true.

¹ 'Notes upon a Case of Obsessional Neurosis' (1909*d*).

One of the most uncanny and wide-spread forms of superstition is the dread of the evil eye, which has been exhaustively studied by the Hamburg oculist Seligmann (1910-11). There never seems to have been any doubt about the source of this dread. Whoever possesses something that is at once valuable and fragile is afraid of other people's envy, in so far as he projects on to them the envy he would have felt in their place. A feeling like this betrays itself by a look even though it is not put into words; and when a man is prominent owing to noticeable, and particularly owing to unattractive, attributes, other people are ready to believe that his envy is rising to a more than usual degree of intensity and that this intensity will convert it into effective action. What is feared is thus a secret intention of doing harm, and certain signs are taken to mean that that intention has the necessary power at its command.

These last examples of the uncanny are to be referred to the principle which I have called 'omnipotence of thoughts', taking the name from an expression used by one of my patients. And now we find ourselves on familiar ground. Our analysis of instances of the uncanny has led us back to the old, animistic conception of the universe. This was characterized by the idea that the world was peopled with the spirits of human beings; by the subject's narcissistic overvaluation of his own mental processes; by the belief in the omnipotence of thoughts and the technique of magic based on that belief; by the attribution to various outside persons and things of carefully graded magical powers, or '*mana*'; as well as by all the other creations with the help of which man, in the unrestricted narcissism of that stage of development, strove to fend off the manifest prohibitions of reality. It seems as if each one of us has been through a phase of individual development corresponding to this animistic stage in primitive men, that none of us has passed through it without preserving certain residues and traces of it which are still capable of manifesting themselves, and that everything which now strikes us as 'uncanny' fulfils the condition of touching those residues of animistic mental activity within us and bringing them to expression.¹

At this point I will put forward two considerations which, I think, contain the gist of this short study. In the first place, if psycho-analytic theory is correct in maintaining that every affect belonging to an emotional impulse, whatever its kind, is transformed, if it is repressed, into anxiety, then among instances of frightening things there must be one class in which the frightening element can be shown to be something repressed which *recurs*. This class of frightening things would then constitute the uncanny; and it must be a matter of indifference whether what is uncanny was itself originally frightening or whether it carried some *other* affect. In the second place, if this is indeed the secret nature of the uncanny, we can understand why linguistic usage has extended *das Heimliche* into its opposite, *das Unheimliche* (p. 3680); for this uncanny is in reality nothing new or alien, but something which is familiar and old-established in the mind and which has become alienated from it only through the process of repression. This reference to the factor of repression enables us, furthermore, to understand Schelling's definition of the uncanny as something which ought to have remained hidden but has come to light.

¹ Cf. my book *Totem and Taboo* (1912-13), Essay III, 'Animism, Magic and the Omnipotence of Thoughts', where the following footnote will be found: 'We appear to attribute an "uncanny" quality to impressions that seek to confirm the omnipotence of thoughts and the animistic mode of thinking in general, after we have reached a stage at which, in our *judgement*, we have abandoned such beliefs.'

It only remains for us to test our new hypothesis on one or two more examples of the uncanny.

Many people experience the feeling in the highest degree in relation to death and dead bodies, to the return of the dead, and to spirits and ghosts. As we have seen some languages in use to-day can only render the German expression 'an *unheimlich* house' by 'a *haunted* house'. We might indeed have begun our investigation with this example, perhaps the most striking of all, of something uncanny, but we refrained from doing so because the uncanny in it is too much intermixed with what is purely gruesome and is in part overlaid by it. There is scarcely any other matter, however, upon which our thoughts and feelings have changed so little since the very earliest times, and in which discarded forms have been so completely preserved under a thin disguise, as our relation to death. Two things account for our conservatism: the strength of our original emotional reaction to death and the insufficiency of our scientific knowledge about it. Biology has not yet been able to decide whether death is the inevitable fate of every living being or whether it is only a regular but yet perhaps avoidable event in life. It is true that the statement 'All men are mortal' is paraded in text-books of logic as an example of a general proposition; but no human being really grasps it, and our unconscious has as little use now as it ever had for the idea of its own mortality. Religions continue to dispute the importance of the undeniable fact of individual death and to postulate a life after death; civil governments still believe that they cannot maintain moral order among the living if they do not uphold the prospect of a better life hereafter as a recompense for mundane existence. In our great cities, placards announce lectures that undertake to tell us how to get into touch with the souls of the departed; and it cannot be denied that not a few of the most able and penetrating minds among our men of science have come to the conclusion, especially towards the close of their own lives, that a contact of this kind is not impossible. Since almost all of us still think as savages do on this topic, it is no matter for surprise that the primitive fear of the dead is still so strong within us and always ready to come to the surface on any provocation. Most likely our fear still implies the old belief that the dead man becomes the enemy of his survivor and seeks to carry him off to share his new life with him. Considering our unchanged attitude towards death, we might rather enquire what has become of the repression, which is the necessary condition of a primitive feeling recurring in the shape of something uncanny. But repression is there, too. All supposedly educated people have ceased to believe officially that the dead can become visible as spirits, and have made any such appearances dependent on improbable and remote conditions; their emotional attitude towards their dead, moreover, once a highly ambiguous and ambivalent one, has been toned down in the higher strata of the mind into an unambiguous feeling of piety.¹

¹ Cf. *Totem and Taboo*.

We have now only a few remarks to add - for animism, magic and sorcery, the omnipotence of thoughts, man's attitude to death, involuntary repetition and the castration complex comprise practically all the factors which turn something frightening into something uncanny.

We can also speak of a living person as uncanny, and we do so when we ascribe evil intentions to him. But that is not all; in addition to this we must feel that his intentions to harm us are going to be carried out with the help of special powers. A good instance of this is the '*Gettatore*', that uncanny figure of Romanic superstition which Schaeffer, with intuitive poetic feeling and profound psycho-analytic understanding, has transformed into a sympathetic character in his *Josef Montfort*. But the question of these secret powers brings us back again to the realm of animism. It was the pious Gretchen's intuition that Mephistopheles possessed secret powers of this kind that made him so uncanny to her.

Sie fühlt dass ich ganz sicher ein Genie,
Vielleicht sogar der Teufel bin.¹

The uncanny effect of epilepsy and of madness has the same origin. The layman sees in them the working of forces hitherto unsuspected in his fellow-men, but at the same time he is dimly aware of them in remote corners of his own being. The Middle Ages quite consistently ascribed all such maladies to the influence of demons, and in this their psychology was almost correct. Indeed, I should not be surprised to hear that psycho-analysis, which is concerned with laying bare these hidden forces, has itself become uncanny to many people for that very reason. In one case, after I had succeeded - though none too rapidly - in effecting a cure in a girl who had been an invalid for many years, I myself heard this view expressed by the patient's mother long after her recovery.

¹ [She feels that surely I'm a genius now, -
Perhaps the very Devil indeed!]

Dismembered limbs, a severed head, a hand cut off at the wrist, as in a fairy tale of Hauff's, feet which dance by themselves, as in the book by Schaeffer which I mentioned above - all these have something peculiarly uncanny about them, especially when, as in the last instance, they prove capable of independent activity in addition. As we already know, this kind of uncanniness springs from its proximity to the castration complex. To some people the idea of being buried alive by mistake is the most uncanny thing of all. And yet psycho-analysis has taught us that this terrifying phantasy is only a transformation of another phantasy which had originally nothing terrifying about it at all, but was qualified by a certain lasciviousness - the phantasy, I mean, of intra-uterine existence.

There is one more point of general application which I should like to add, though, strictly speaking, it has been included in what has already been said about animism and modes of working of the mental apparatus that have been surmounted; for I think it deserves special emphasis. This is that an uncanny effect is often and easily produced when the distinction between imagination and reality is effaced, as when something that we have hitherto regarded as imaginary appears before us in reality, or when a symbol takes over the full functions of the thing it symbolizes, and so on. It is this factor which contributes not a little to the uncanny effect attaching to magical practices. The infantile element in this, which also dominates the minds of neurotics, is the over-accentuation of psychical reality in comparison with material reality - a feature closely allied to the belief in the omnipotence of thoughts. In the middle of the isolation of war-time a number of the English *Strand Magazine* fell into my hands; and, among other somewhat redundant matter, I read a story about a young married couple who move into a furnished house in which there is a curiously shaped table with carvings of crocodiles on it. Towards evening an intolerable and very specific smell begins to pervade the house; they stumble over something in the dark; they seem to see a vague form gliding over the stairs - in short, we are given to understand that the presence of the table causes ghostly crocodiles to haunt the place, or that the wooden monsters come to life in the dark, or something of the sort. It was a naïve enough story, but the uncanny feeling it produced was quite remarkable.

To conclude this collection of examples, which is certainly not complete, I will relate an instance taken from psycho-analytic experience; if it does not rest upon mere coincidence, it furnishes a beautiful confirmation of our theory of the uncanny. It often happens that neurotic men declare that they feel there is something uncanny about the female genital organs. This *unheimlich* place, however, is the entrance to the former *Heim* of all human beings, to the place where each one of us lived once upon a time and in the beginning. There is a joking saying that 'Love is home-sickness'; and whenever a man dreams of a place or a country and says to himself, while he is still dreaming: 'this place is familiar to me, I've been here before', we may interpret the place as being his mother's genitals or her body. In this case too, then, the *unheimlich* is what was once *heimlich*, familiar; the prefix '*un*' is the token of repression.

III

In the course of this discussion the reader will have felt certain doubts arising in his mind; and he must now have an opportunity of collecting them and bringing them forward.

It may be true that the uncanny is something which is secretly familiar, which has undergone repression and then returned from it, and that everything that is uncanny fulfils this condition. But the selection of material on this basis does not enable us to solve the problem of the uncanny. For our proposition is clearly not convertible. Not everything that fulfils this condition - not everything that recalls repressed desires and surmounted modes of thinking belonging to the prehistory of the individual and of the race - is on that account uncanny.

Nor shall we conceal the fact that for almost every example adduced in support of our hypothesis one may be found which rebuts it. The story of the severed hand in Hauff's fairy tale certainly has an uncanny effect, and we have traced that effect back to the castration complex; but most readers will probably agree with me in judging that no trace of uncanniness is provoked by Herodotus's story of the treasure of Rhampsinitus, in which the master-thief, whom the princess tries to hold fast by the hand, leaves his brother's severed hand behind with her instead. Again, the prompt fulfilment of the wishes of Polycrates undoubtedly affects us in the same uncanny way as it did the king of Egypt; yet our own fairy stories are crammed with instantaneous wish-fulfilments which produce no uncanny effect whatever. In the story of 'The Three Wishes', the woman is tempted by the savoury smell of a sausage to wish that she might have one too, and in an instant it lies on a plate before her. In his annoyance at her hastiness her husband wishes it may hang on her nose. And there it is, dangling from her nose. All this is very striking but not in the least uncanny. Fairy tales quite frankly adopt the animistic standpoint of the omnipotence of thoughts and wishes, and yet I cannot think of any genuine fairy story which has anything uncanny about it. We have heard that it is in the highest degree uncanny when an inanimate object - a picture or a doll - comes to life; nevertheless in Hans Andersen's stories the household utensils, furniture and tin soldiers are alive, yet nothing could well be more remote from the uncanny. And we should hardly call it uncanny when Pygmalion's beautiful statue comes to life.

Apparent death and the re-animation of the dead have been represented as most uncanny themes. But things of this sort too are very common in fairy stories. Who would be so bold as to call it uncanny, for instance, when Snow-White opens her eyes once more? And the resuscitation of the dead in accounts of miracles, as in the New Testament, elicits feelings quite unrelated to the uncanny. Then, too, the theme that achieves such an indubitably uncanny effect, the unintended recurrence of the same thing, serves other and quite different purposes in another class of cases. We have already come across one example in which it is employed to call up a feeling of the comic; and we could multiply instances of this kind. Or again, it works as a means of emphasis, and so on. And once more: what is the origin of the uncanny effect of silence, darkness and solitude? Do not these factors point to the part played by danger in the genesis of what is uncanny, notwithstanding that in children these same factors are the most frequent determinants of the expression of fear? And are we after all justified in entirely ignoring intellectual uncertainty as a factor, seeing that we have admitted its importance in relation to death?

It is evident therefore, that we must be prepared to admit that there are other elements besides those which we have so far laid down as determining the production of uncanny feelings. We might say that these preliminary results have satisfied *psycho-analytic* interest in the problem of the uncanny, and that what remains probably calls for an *aesthetic* enquiry. But that would be to open the door to doubts about what exactly is the value of our general contention that the uncanny proceeds from something familiar which has been repressed.

We have noticed one point which may help us to resolve these uncertainties: nearly all the instances that contradict our hypothesis are taken from the realm of fiction, of imaginative writing. This suggests that we should differentiate between the uncanny that we actually experience and the uncanny that we merely picture or read about.

What is *experienced* as uncanny is much more simply conditioned but comprises far fewer instances. We shall find, I think, that it fits in perfectly with our attempt at a solution, and can be traced back without exception to something familiar that has been repressed. But here, too, we must make a certain important and psychologically significant differentiation in our material, which is best illustrated by turning to suitable examples.

Let us take the uncanny associated with the omnipotence of thoughts, with the prompt fulfilment of wishes, with secret injurious powers and with the return of the dead. The condition under which the feeling of uncanniness arises here is unmistakable. We - or our primitive forefathers - once believed that these possibilities were realities, and were convinced that they actually happened. Nowadays we no longer believe in them, we have *surmounted* these modes of thought; but we do not feel quite sure of our new beliefs, and the old ones still exist within us ready to seize upon any confirmation. As soon as something *actually happens* in our lives which seems to confirm the old, discarded beliefs we get a feeling of the uncanny; it is as though we were making a judgement something like this: 'So, after all, it is *true* that one can kill a person by the mere wish!' or, 'So the dead *do* live on and appear on the scene of their former activities!' and so on. Conversely, anyone who has completely and finally rid himself of animistic beliefs will be insensible to this type of the uncanny. The most remarkable coincidences of wish and fulfilment, the most mysterious repetition of similar experiences in a particular place or on a particular date, the most deceptive sights and suspicious noises - none of these things will disconcert him or raise the kind of fear which can be described as 'a fear of something uncanny'. The whole thing is purely an affair of 'reality-testing', a question of the material reality of the phenomena.¹

¹ Since the uncanny effect of a 'double' also belongs to this same group it is interesting to observe what the effect is of meeting one's own image unbidden and unexpected. Ernst Mach has related two such observations in his *Analyse der Empfindungen* (1900, 3). On the first occasion he was not a little startled when he realized that the face before him was his own. The second time he formed a very unfavourable opinion about the supposed stranger who entered the omnibus, and thought 'What a shabby-looking school-master that man is who is getting in!' - I can report a similar adventure. I was sitting alone in my *wagon-lit* compartment when a more than usually violent jolt of the train swung back the door of the adjoining washing-cabinet, and an elderly gentleman in a dressing-gown and a travelling cap came in. I assumed that in leaving the washing-cabinet, which lay between the two compartments, he had taken the wrong direction and come into my compartment by mistake. Jumping up with the intention of putting him right, I at once realized to my dismay that the intruder was nothing but my own reflection in the looking-glass on the open door. I can still recollect that I thoroughly disliked his appearance. Instead, therefore, of being *frightened* by our 'doubles', both Mach and I simply failed to recognize them as such. Is it not possible, though, that our dislike of them was a vestigial trace of the archaic reaction which feels the 'double' to be something uncanny?

The state of affairs is different when the uncanny proceeds from repressed infantile complexes, from the castration complex, womb-phantasies, etc.; but experiences which arouse this kind of uncanny feeling are not of very frequent occurrence in real life. The uncanny which proceeds from actual experience belongs for the most part to the first group. Nevertheless the distinction between the two is theoretically very important. Where the uncanny comes from infantile complexes the question of material reality does not arise; its place is taken by psychical reality. What is involved is an actual repression of some content of thought and a return of this repressed content, not a cessation of *belief in the reality* of such a content. We might say that in the one case what had been repressed is a particular ideational content, and in the other the belief in its (material) reality. But this last phrase no doubt extends the term 'repression' beyond its legitimate meaning. It would be more correct to take into account a psychological distinction which can be detected here, and to say that the animistic beliefs of civilized people are in a state of having been (to a greater or lesser extent) *surmounted*. Our conclusion could then be stated thus: an uncanny experience occurs either when infantile complexes which have been repressed are once more revived by some impression, or when primitive beliefs which have been surmounted seem once more to be confirmed. Finally, we must not let our predilection for smooth solutions and lucid exposition blind us to the fact that these two classes of uncanny experience are not always sharply distinguishable. When we consider that primitive beliefs are most intimately connected with infantile complexes, and are, in fact, based on them, we shall not be greatly astonished to find that the distinction is often a hazy one.

The uncanny as it is depicted in *literature*, in stories and imaginative productions, merits in truth a separate discussion. Above all, it is a much more fertile province than the uncanny in real life, for it contains the whole of the latter and something more besides, something that cannot be found in real life. The contrast between what has been repressed and what has been surmounted cannot be transposed on to the uncanny in fiction without profound modification; for the realm of phantasy depends for its effect on the fact that its content is not submitted to reality-testing. The somewhat paradoxical result is that *in the first place a great deal that is not uncanny in fiction would be so if it happened in real life; and in the second place, that there are many more means of creating uncanny effects in fiction than there are in real life.*

The imaginative writer has this licence among many others, that he can select his world of representation so that it either coincides with the realities we are familiar with or departs from them in what particulars he pleases. We accept his ruling in every case. In fairy tales, for instance, the world of reality is left behind from the very start, and the animistic system of beliefs is frankly adopted. Wish-fulfilments, secret powers, omnipotence of thoughts, animation of inanimate objects, all the elements so common in fairy stories, can exert no uncanny influence here; for, as we have learnt, that feeling cannot arise unless there is a conflict of judgement as to whether things which have been 'surmounted' and are regarded as incredible may not, after all, be possible; and this problem is eliminated from the outset by the postulates of the world of fairy tales. Thus we see that fairy stories, which have furnished us with most of the contradictions to our hypothesis of the uncanny, confirm the first part of our proposition - that in the realm of fiction many things are not uncanny which would be so if they happened in real life. In the case of these stories there are other contributory factors, which we shall briefly touch upon later.

The creative writer can also choose a setting which though less imaginary than the world of fairy tales, does yet differ from the real world by admitting superior spiritual beings such as daemonic spirits or ghosts of the dead. So long as they remain within their setting of poetic reality, such figures lose any uncanniness which they might possess. The souls in Dante's *Inferno*, or the supernatural apparitions in Shakespeare's *Hamlet*, *Macbeth* or *Julius Caesar*, may be gloomy and terrible enough, but they are no more really uncanny than Homer's jovial world of gods. We adapt our judgement to the imaginary reality imposed on us by the writer, and regard souls, spirits and ghosts as though their existence had the same validity as our own has in material reality. In this case too we avoid all trace of the uncanny.

The situation is altered as soon as the writer pretends to move in the world of common reality. In this case he accepts as well all the conditions operating to produce uncanny feelings in real life; and everything that would have an uncanny effect in reality has it in his story. But in this case he can even increase his effect and multiply it far beyond what could happen in reality, by bringing about events which never or very rarely happen in fact. In doing this he is in a sense betraying us to the superstitiousness which we have ostensibly surmounted; he deceives us by promising to give us the sober truth, and then after all overstepping it. We react to his inventions as we would have reacted to real experiences; by the time we have seen through his trick it is already too late and the author has achieved his object. But it must be added that his success is not unalloyed. We retain a feeling of dissatisfaction, a kind of grudge against the attempted deceit. I have noticed this particularly after reading Schnitzler's *Die Weissagung* and similar stories which flirt with the supernatural. However, the writer has one more means which he can use in order to avoid our recalcitrance and at the same time to improve his chances of success. He can keep us in the dark for a long time about the precise nature of the presuppositions on which the world he writes about is based, or he can cunningly and ingeniously avoid any definite information on the point to the last. Speaking generally, however, we find a confirmation of the second part of our proposition - that fiction presents more opportunities for creating uncanny feelings than are possible in real life.

Strictly speaking, all these complications relate only to that class of the uncanny which proceeds from forms of thought that have been surmounted. The class which proceeds from repressed complexes is more resistant and remains as powerful in fiction as in real experience, subject to one exception. The uncanny belonging to the first class - that proceeding from forms of thought that have been surmounted retains its character not only in experience but in fiction as well, so long as the setting is one of material reality; but where it is given an arbitrary and artificial setting in fiction, it is apt to lose that character.

We have clearly not exhausted the possibilities of poetic licence and the privileges enjoyed by story-writers in evoking or in excluding an uncanny feeling. In the main we adopt an unvarying passive attitude towards real experience and are subject to the influence of our physical environment. But the story-teller has a *peculiarly* directive power over us; by means of the moods he can put us into, he is able to guide the current of our emotions, to dam it up in one direction and make it flow in another, and he often obtains a great variety of effects from the same material. All this is nothing new, and has doubtless long since been fully taken into account by students of aesthetics. We have drifted into this field of research half involuntarily, through the temptation to explain certain instances which contradicted our theory of the causes of the uncanny. Accordingly we will now return to the examination of a few of those instances.

We have already asked why it is that the severed hand in the story of the treasure of Rhampsinitus has no uncanny effect in the way that the severed hand has in Hauff's story. The question seems to have gained in importance now that we have recognized that the class of the uncanny which proceeds from repressed complexes is the more resistant of the two. The answer is easy. In the Herodotus story our thoughts are concentrated much more on the superior cunning of the master-thief than on the feelings of the princess. The princess may very well have had an uncanny feeling, indeed she very probably fell into a swoon; but we have no such sensations, for we put ourselves in the thief's place, not in hers. In Nestroy's farce, *Der Zerrissene*, another means is used to avoid any impression of the uncanny in the scene in which the fleeing man, convinced that he is a murderer, lifts up one trap door after another and each time sees what he takes to be the ghost of his victim rising up out of it. He calls out in despair, 'But I've only killed *one* man. Why this ghastly multiplication?' We know what went before this scene and do not share his error, so what must be uncanny to him has an irresistibly comic effect on us. Even a 'real' ghost, as in Oscar Wilde's *Canterville Ghost*, loses all power of at least arousing *gruesome* feelings in us as soon as the author begins to amuse himself by being ironical about it and allows liberties to be taken with it. Thus we see how independent emotional effects can be of the actual subject-matter in the world of fiction. In fairy stories feelings of fear - including therefore uncanny feelings - are ruled out altogether. We understand this, and that is why we ignore any opportunities we find in them for developing such feelings.

Concerning the factors of silence, solitude and darkness, we can only say that they are actually elements in the production of the infantile anxiety from which the majority of human beings have never become quite free. This problem has been discussed from a psycho-analytic point of view elsewhere.

PREFACE TO REIK'S *RITUAL: PSYCHO-ANALYTIC STUDIES*
(1919)

Intentionally left blank

PREFACE TO REIK'S *RITUAL: PSYCHO-ANALYTIC STUDIES*

Psycho-analysis was born out of medical necessity. It sprang from the need for bringing help to neurotic patients, who had found no relief through rest-cures, through the arts of hydropathy or through electricity. A most remarkable observation made by Josef Breuer had excited a hope that the more one understood of the hitherto unexplored origin of their symptoms the more extensive would be the help one could afford them. Thus it came about that psycho-analysis, being originally a purely medical technique, was from the first directed towards research, towards the discovery of causal chains at once far-reaching and reconducive.

Its further course led it away from the study of the somatic determinants of nervous disease to an extent that was bewildering to physicians. Instead, it was brought into contact with the mental substance of human lives - the lives not only of the sick, but of the healthy, the normal and the supernormal. It had to deal with emotions and passions, and most of all with those which the poets never tire of depicting and celebrating - the emotions of love. It learnt to recognize the power of memories, the unsuspected importance of the years of childhood in shaping the adult, and the strength of wishes, which falsify human judgements and lay down fixed lines for human endeavour.

For a time psycho-analysis seemed fated to merge into psychology without being able to show why the psychology of the sick differed from that of the normal. In the course of its advance, however, it came up against the problem of dreams, which are abnormal products of the mind created by normal men under regularly recurrent physiological conditions. When psycho-analysis had solved the problem of dreams, it had discovered in *unconscious* psychical processes the common ground in which the highest and the lowest of mental impulses have their roots and from which spring the most normal as well as the most morbid and erratic of mental productions. The new picture of the workings of the mind began to grow ever clearer and more complete. It was a picture of obscure instinctual forces organic in origin, striving towards inborn aims, and, above them, of an agency comprising more highly organized mental structures - acquisitions of human evolution made under the impact of human history -, an agency which has taken over portions of the instinctual impulses, has developed them further or has even directed them towards higher aims, but which in any case binds them firmly and manipulates their energy to suit its own purposes. This higher organization, however, which is known to us as the ego, has rejected another portion of these same elementary instinctual impulses as being unserviceable because they cannot be fitted into the organic unity of the individual or because they rebel against the individual's cultural aims. The ego is not in a position to exterminate these unsubdued mental powers, but it turns its back on them, lets them remain at the lowest psychological level, defends itself from their demands by the energetic erection of protective and antithetical barriers or seeks to come to terms with them by means of substitutive satisfactions. These instincts which have fallen victim to repression - untamed and indestructible, yet inhibited from any kind of activity - together with their primitive mental representatives, constitute the mental underworld, the nucleus of the true unconscious, and are at every moment ready to assert their demands and, by hook or by crook, to force their way forward to satisfaction. To this is due the instability of the proud superstructure of the mind, the emergence at night of the proscribed and repressed material in the form of dreams, and the tendency to fall ill with neuroses and psychoses as soon as the balance of power between the ego and the repressed shifts to the disadvantage of the ego.

A little reflection was bound to show that it would be impossible to restrict to the provinces of dreams and nervous disorders a view such as this of the life of the human mind. If that view has hit upon a truth, it must apply equally to *normal* mental events, and even the highest achievements of the human spirit must bear a demonstrable relation to the factors found in pathology - to repression, to the efforts at mastering the unconscious and to the possibilities of satisfying the primitive instincts. There was thus an irresistible temptation and, indeed, a scientific duty, to apply the research methods of psycho-analysis, in regions far remote from its native soil, to the various mental sciences. And indeed psycho-analytic work upon patients itself pointed persistently in the direction of this new task, for it was obvious that the forms assumed by the different neuroses echoed the most highly admired productions of our culture. Thus hysterics are undoubtedly imaginative artists, even if they express their phantasies *mimetically* in the main and without considering their intelligibility to other people; the ceremonials and prohibitions of obsessional neurotics drive us to suppose that they have created a private religion of their own; and the delusions of paranoics have an unpalatable external similarity and internal kinship to the systems of our philosophers. It is impossible to escape the conclusion that these patients are, in an *asocial* fashion, making the very attempts at solving their conflicts and appeasing their pressing needs which, when those attempts are carried out in a fashion that is acceptable to the majority, are known as poetry, religion and philosophy.

In 1913 Otto Rank and Hanns Sachs, in an extremely interesting work, brought together the results which had been achieved up to that time in the application of psycho-analysis to the mental sciences. The most easily accessible branches of those sciences seem to be mythology and the history of literature and religion. No final formula has yet been found enabling us to give an appropriate place to myths in this connection. Otto Rank, in a large volume on the incest complex (1912), has produced evidence of the surprising fact that the choice of subject matter, especially for dramatic works, is principally determined by the ambit of what psycho-analysis has termed the 'Oedipus complex'. By working it over with the greatest variety of modifications, distortions and disguises, the dramatist seeks to deal with his own most personal relations to this emotional theme. It is in attempting to master the Oedipus complex - that is to say, a person's emotional attitude towards his family, or in a narrower sense towards his father and mother - that individual neurotics come to grief, and for this reason that complex habitually forms the nucleus of their neuroses. It does not owe its importance to any unintelligible conjunction; the emphasis laid upon the relation of children to their parents is an expression of the biological facts that the young of the human race pass through a long period of dependence and are slow in reaching maturity, as well as that their capacity for love undergoes a complicated course of development. Consequently, the overcoming of the Oedipus complex coincides with the most efficient way of mastering the archaic, animal heritage of humanity. It is true that that heritage comprises all the forces that are required for the subsequent cultural development of the individual, but they must first be sorted out and worked over. This archaic heirloom is not fit to be used for the purposes of civilized social life in the form in which it is inherited by the individual.

To find the starting-point for the psycho-analytic view of religious life we must go a step further. What is to-day the heritage of the individual was once a new acquisition and has been handed on from one to another of a long series of generations. Thus the Oedipus complex too may have had stages of development, and the study of prehistory may enable us to trace them out. Investigation suggests that life in the human family took a quite different form in those remote days from that with which we are now familiar. And this idea is supported by findings based on observations of contemporary primitive races. If the prehistoric and ethnological material on this subject is worked over psycho-analytically, we arrive at an unexpectedly precise result: namely that God the Father once walked upon earth in bodily form and exercised his sovereignty as chieftain of the primal human horde until his sons united to slay him. It emerges further that this crime of liberation and the reactions to it had as their result the appearance of the first social ties, the basic moral restrictions and the oldest form of religion, totemism. But the later religions too have the same content, and on the one hand they are concerned with obliterating the traces of that crime or with expiating it by bringing forward other solutions of the struggle between the father and sons, while on the other hand they cannot avoid repeating once more the elimination of the father. Incidentally, an echo of this monstrous event, which overshadowed the whole course of human development, is also to be found in myths.

This hypothesis, which is founded on the observations of Robertson Smith and was developed by me in *Totem and Taboo*, has been taken by Theodor Reik as the basis of his studies on the problems of the psychology of religion, of which this is the first volume. In accordance with psycho-analytic technique these studies start out from hitherto unexplained details of religious life, and by means of their elucidation gain access to the fundamental postulates and ultimate aims of religions; moreover they keep steadily in view the relation between prehistoric man and contemporary primitive societies as well as the connection between the products of civilization and the substitutive structures of neurotics. In conclusion, I would draw attention to the author's own introduction and express my belief that his work will recommend itself to the notice of specialists in the branch of knowledge with which it deals.

A NOTE ON PSYCHO-ANALYTIC PUBLICATIONS AND PRIZES (1919)

In the Autumn of 1918 a member of the Budapest Psycho-Analytical Society informed me that a Fund had been set aside for cultural purposes from the profits made by industrial undertakings during the war. The decision as to its use lay jointly with himself and the Chief Burgermaster of the city of Budapest, Dr. Stephan Bárczy. They had agreed to devote the considerable sum of money concerned to the purposes of the psycho-analytic movement and to hand over its administration to me. I accepted this commission, and I now fulfil my duty of offering public thanks to the Chief Burgermaster (who soon afterwards received the Psycho-Analytical Congress in Budapest with so much honour) as well as to the anonymous member who has performed such a high service to the cause of psycho-analysis.

The Fund thus placed at my disposal, which was given my name, was allotted by me to the foundation of an international psycho-analytic publishing business. I considered that in the present circumstances this was our most important need.

Unlike many other scientific undertakings, our two periodical publications, the *Internationale Zeitschrift für ärztliche Psychoanalyse* and *Imago*, did not come to an end during the war. We succeeded in keeping them in existence, but in consequence of the increasing difficulties, closing of frontiers and rise in prices which accompanied the war, it became necessary to reduce them considerably in size and to allow undesirably long intervals to elapse between the publication of successive issues. Of the four editors of the two journals (Ferenczi, Jones, Rank and Sachs) one, being a subject of an enemy State, was cut off from us; two others had joined the forces and were fully engaged in their military duties; only Dr. Sachs was left at work, and he self-sacrificingly assumed the whole burden. A few of the local psycho-analytical societies found it necessary to suspend their meetings entirely; the number of contributors shrank, as did that of the subscribers. It was easy to foresee that the publisher's natural dissatisfaction would soon put in question the continuance of the journals to which we attached so much importance. Yet numerous indications, which reached us even from the front-line trenches, pointed to the fact that contemporary interest in psycho-analysis had not diminished. I think I was justified in my intention to put an end to these difficulties and dangers by the foundation of an international psycho-analytic publishing business. This publishing house is already in existence to-day, as a limited liability company; it is under the direction of Dr. Otto Rank, who has been for so many years secretary of the Vienna Society and co-editor of the two psycho-analytic journals, and who has returned after many years' absence on active service to his earlier work in the service of psycho-analysis.

The new publishing house, supported by the funds of the Budapest endowment, has assumed the task of ensuring the regular appearance and reliable distribution of the two journals. As soon as the difficulties of external circumstances permit, it is intended that they shall be restored to their former dimensions, and that these dimensions may if necessary be increased, without any extra charge to the subscribers. But in addition to this, and without waiting for an improvement, the publishing house will proceed to print books and pamphlets dealing with the field of medical and applied psycho-analysis; and since it is not a profit-making concern, it will be able to pay better heed to the interests of authors than is usually done by commercial publishers.

Simultaneously with the establishment of the psycho-analytic publishing house it was decided to award annual prizes out of the interest on the Budapest endowment, to two outstanding pieces of work, one each in the field of medical and of applied psycho-analysis. These prizes - to the amount of 1,000 Austrian *Kronen* - are intended to be awarded, not to authors, but to individual works, so that there will be a possibility of the same author winning a prize repeatedly. The decision on the question of which among the writings published during a particular period are to receive prizes has not been transferred to a committee but will be kept in the hands of a single person, the Administrator of the fund for the time being; otherwise, if a committee of adjudicators were to be formed of the most experienced and discerning analysts, their own writings would have to be excluded from consideration, and the scheme might easily fail in its intention of distinguishing exemplary achievements in psycho-analytic literature. If the adjudicator finds himself hesitating between two works of almost equal value, he will be empowered to divide the prize between them, without the award of a half-prize implying any less appreciation of the work in question.

It is intended that these prizes shall in general be awarded every year and that the choice should lie between the whole of the psycho-analytically important literature published during that period, irrespectively of whether the author of the work in question is a Member of the International Psycho-Analytical Association.

The first prizes have already been awarded and relate to papers published during the period of the war, from 1914 to 1918. The prize for medical psycho-analysis has been divided between Karl Abraham's paper 'The First Preenital Stage of the Libido' (1916) and Ernst Simmel's pamphlet *Kriegsneurosen und psychisches Trauma* (1918). The prize for applied psycho-analysis has been awarded to Theodor Reik's paper 'Die Pubertätsriten der Wilden' (1915).

FREUD.

[Two further announcements on the same subject appeared subsequently: 'Preiszuteilungen' (*Int. Z. Psychoanal.*, **7**, 381 [1921]), and 'Preisausschreibung' (*ibid.*, **8**, 527 [1922]).]

‘AWARD OF PRIZES

‘A recent gift made by Dr. Max Eitingon, the director of the Berlin Clinic, has made it possible for me to revive the award of prizes (first made in 1919) for psycho-analytic writings of peculiar merit. The prize for *medical* psycho-analysis has been awarded to A. Stärcke (of Den Dolder, Holland) for his two publications "Der Kastrationskomplex" and "Psychoanalyse und Psychiatrie" (both of them Congress papers), of which the first appeared in the current volume of this periodical and the second as a supplementary issue. The prize for *applied* psycho-analysis has gone to Dr. G. Róheim (of Budapest) for his paper "Das Selbst" and his Congress paper on Australian Totemism. The amount of each prize was one thousand marks.

FREUD.’

‘PRIZE OFFER

‘At the Seventh International Psycho-Analytical Congress, in Berlin, I laid down as the subject for a prize: "The Relation between Analytic Technique and Analytic Theory." The questions to be discussed are how far the technique has influenced the theory and how far they assist or hinder each other at the present time.

‘Works dealing with this subject should be sent to me at the address given below before May 1, 1923. They should be legibly typewritten. They should have a motto attached and should be accompanied by a sealed envelope enclosing the author's name. They must be written either in German or English. In judging the works submitted I shall have the assistance of Dr. K. Abraham and Dr. M. Eitingon.

‘The prize amounts to 20,000 marks at the value current at the time of the Congress.

‘Berggasse 19, Vienna IX.

FREUD.’

JAMES J. PUTNAM
(1919)

Among the first pieces of news to reach us after the raising of the barrier separating us from the Anglo-Saxon countries comes the painful report of the death of Putnam, the President of the great pan-American psycho-analytic group. He lived to be over seventy-two years old, remained intellectually active to the end, and died peacefully of heart-failure during his sleep in November 1918. Putnam, who was until a few years ago Professor of Neuropathology at Harvard University, was the great support of psycho-analysis in America. His numerous theoretical works (a few of which made their first appearance in the *Internationale Zeitschrift*) have, by their clarity and wealth of ideas, and by the decisively favourable line they took, contributed immensely towards creating the high esteem which psycho-analysis now enjoys in America both in psychiatric teaching and in public opinion. His example may have been no less effective. He was universally respected for his unimpeachable character, and it was recognized that he was influenced only by the highest ethical considerations. His closer personal acquaintances could not escape the conclusion that he was one of those happily compensated people of the obsessional type for whom what is noble is second nature and for whom any concession to unworthiness has become an impossibility.

J. J. Putnam's personal appearance was made familiar to European analysts through the part he took in the Weimar Congress of 1911. The editor of the *Zeitschrift* hopes to include in its next issue a portrait of our honoured friend and a detailed appreciation of his scientific achievements.

[Freud also translated one of Putnam's papers (1910) anonymously and added the following footnote to the translation (*Zbl. Psychoan.*, 1 (1911), 137): 'This lecture delivered by the Professor of Neurology at Boston University is offered to our readers as an offset to the many unjust and uncomprehending attacks that are levelled against psycho-analysis, in place of counter-criticisms which might easily lead to embittered feelings. J. Putnam is not only one of the most eminent neurologists in America but also a man everywhere greatly respected for his unimpeachable character and high moral standards. Although he has left his youth far behind him, he took his open stand last year in the front rank of the champions of psycho-analysis.']

VICTOR TAUSK (1919)

Among the sacrifices, fortunately few in number, claimed by the war from the ranks of psycho-analysis, we must count Dr. Victor Tausk. This rarely-gifted man, a Vienna specialist in nervous diseases, took his own life before peace was signed.

Dr. Tausk, who was only in his forty-second year, had for more than ten years been one of the closer circle of Freud's followers. Originally a lawyer by profession, he had for some considerable time been acting as a magistrate in Bosnia when, under the stress of severe personal troubles, he abandoned his career and turned to journalism, for which he was peculiarly suited by his wide general education. After working for some time as a journalist in Berlin, he came to Vienna in the same capacity. Here he became acquainted with psycho-analysis and soon decided to devote himself to it entirely. Although he was no longer a young man and was the father of a family, he was not deterred by the great difficulties and sacrifices involved in yet another change in profession, and one which must necessitate an interruption of several years before he could once more earn his living. For he embarked on the tedious study of medicine only as a means to enable him to carry on a psycho-analytic practice.

Shortly before the outbreak of the World War, Tausk had obtained his second doctor's degree and set up in Vienna as a nerve-specialist. Here, after a relatively short time, he had begun building up a considerable practice and had achieved some excellent results. These activities promised the rising young doctor full satisfaction as well as a means of support; but he was all at once violently torn from them by the war. He was called up immediately for active service and soon promoted to senior rank. He carried out his medical duties with devotion in the various theatres of war in the North and in the Balkans (finally in Belgrade), and received official commendation. It is also greatly to his honour that during the war he threw himself wholeheartedly, and with complete disregard of the consequences, into exposing the numerous abuses which so many doctors unfortunately tolerated in silence or for which they even shared the responsibility.

The stresses of many years' service in the field could not fail to exercise a severely damaging psychological effect on so intensely conscientious a man. At the last Psycho-Analytical Congress, which we held in Budapest in September 1918 and which brought analysts together once more after many years of separation, Dr. Tausk, who had long been suffering from physical ill-health, was already showing signs of unusual nervous irritability. When, soon afterwards, in the late autumn of last year, he came to the end of his military service and returned to Vienna, he was faced for the third time, in his state of mental exhaustion, with the hard task of building up a new existence - this time under the most unfavourable internal and external conditions. In addition to this, Dr. Tausk, who has left two grown-up sons to whom he was a devoted father, was on the brink of contracting a new marriage. He was no longer able to cope with the many demands imposed on him in his ailing state by harsh reality. On the morning of July 3rd he put an end to his life.

Dr. Tausk had been a member of the Vienna Psycho Analytical Society since the autumn of 1909. He was well known to the readers of this journal from his numerous contributions, which were distinguished by sharp observation, sound judgement and a particular clearness of expression. These writings exhibit plainly the philosophical training which the author was able so happily to combine with the exact methods of science. His strong need to establish things on a philosophical foundation and to achieve epistemological clarity compelled him to formulate, and seek as well to master, the whole profundity and comprehensive meaning of the very difficult problems involved. Perhaps he sometimes went too far in this direction, in his impetuous urge for investigation. Perhaps the time was not yet ripe for laying such general foundations as these for the young science of psycho-analysis. The psycho-analytic consideration of philosophical problems, for which Tausk showed special aptitude, promises to become more and more fruitful. One of his last works, on the psycho-analysis of the function of judgement, which was delivered at the Budapest Congress and has not yet been published, gives evidence of this direction taken by his interest.

In addition to his gift for philosophy and attraction towards it, Tausk possessed a quite exceptional medico-psychological capacity and produced some excellent work in that field too. His clinical activities, to which we owe valuable researches into various psychoses (e.g. melancholia and schizophrenia) justified the fairest hopes and gave him the prospective appointment to a University Lectureship for which he had applied.

Psycho-analysis was particularly indebted to Dr. Tausk, who was a brilliant speaker, for the courses of lectures which he gave over a period of many years to large audiences of both sexes and in which he introduced them to the principles and problems of psycho-analysis. His audiences were able to admire the clarity and didactic skill of his lectures no less than the profundity with which he handled individual topics.

All those who knew him well valued his straightforward character, his honesty towards himself and towards others and the superiority of a nature which was distinguished by a striving for nobility and perfection. His passionate temperament found expression in sharp, and sometimes too sharp, criticisms, which however were combined with a brilliant gift for exposition. These personal qualities exercised a great attraction on many people, and some, too, may have been repelled by them. No one, however, could escape the impression that here was a man of importance.

How much psycho-analysis meant for him, even up to his last moments, is shown by letters which he left behind, in which he expressed his unreserved belief in it and his hope that it will find recognition at a not too distant date. There is no doubt that this man, of whom our science and his friends in Vienna have been prematurely robbed, has contributed to that aim. He is sure of an honourable memory in the history of psycho-analysis and its earliest struggles.

BEYOND THE PLEASURE PRINCIPLE
(1920)

Intentionally left blank

BEYOND THE PLEASURE PRINCIPLE

I

In the theory of psycho-analysis we have no hesitation in assuming that the course taken by mental events is automatically regulated by the pleasure principle. We believe, that is to say, that the course of those events is invariably set in motion by an unpleasurable tension, and that it takes a direction such that its final outcome coincides with a lowering of that tension - that is, with an avoidance of unpleasure or a production of pleasure. In taking that course into account in our consideration of the mental processes which are the subject of our study, we are introducing an 'economic' point of view into our work; and if, in describing those processes, we try to estimate this 'economic' factor in addition to the 'topographical' and 'dynamic' ones, we shall, I think, be giving the most complete description of them of which we can at present conceive, and one which deserves to be distinguished by the term 'metapsychological'.

It is of no concern to us in this connection to enquire how far, with this hypothesis of the pleasure principle, we have approached or adopted any particular, historically established, philosophical system. We have arrived at these speculative assumptions in an attempt to describe and to account for the facts of daily observation in our field of study. Priority and originality are not among the aims that psycho-analytic work sets itself; and the impressions that underlie the hypothesis of the pleasure principle are so obvious that they can scarcely be overlooked. On the other hand we would readily express our gratitude to any philosophical or psychological theory which was able to inform us of the meaning of the feelings of pleasure and unpleasure which act so imperatively upon us. But on this point we are, alas, offered nothing to our purpose. This is the most obscure and inaccessible region of the mind, and, since we cannot avoid contact with it, the least rigid hypothesis, it seems to me, will be the best. We have decided to relate pleasure and unpleasure to the quantity of excitation that is present in the mind but is not in any way 'bound'; and to relate them in such a manner that unpleasure corresponds to an *increase* in the quantity of excitation and pleasure to a *diminution*. What we are implying by this is not a simple relation between the strength of the feelings of pleasure and unpleasure and the corresponding modifications in the quantity of excitation; least of all - in view of all we have been taught by psycho-physiology - are we suggesting any directly proportional ratio: the factor that determines the feeling is probably the amount of increase or diminution in the quantity of excitation *in a given period of time*. Experiment might possibly play a part here; but it is not advisable for us analysts to go into the problem further so long as our way is not pointed by quite definite observations

We cannot, however, remain indifferent to the discovery that an investigator of such penetration as G. T. Fechner held a view on the subject of pleasure and unpleasure which coincides in all essentials with the one that has been forced upon us by psycho-analytic work. Fechner's statement is to be found contained in a small work, *Einige Ideen zur Schöpfungs- und Entwicklungsgeschichte der Organismen*, 1873 (Part XI, Supplement, 94), and reads as follows: 'In so far as conscious impulses always have some relation to pleasure or unpleasure, pleasure and unpleasure too can be regarded as having a psycho-physical relation to conditions of stability and instability. This provides a basis for a hypothesis into which I propose to enter in greater detail elsewhere. According to this hypothesis, every psycho-physical motion rising above the threshold of consciousness is attended by pleasure in proportion as, beyond a certain limit, it approximates to complete stability, and is attended by unpleasure in proportion as, beyond a certain limit, it deviates from complete stability; while between the two limits, which may be described as qualitative thresholds of pleasure and unpleasure, there is a certain margin of aesthetic indifference. . . .'

The facts which have caused us to believe in the dominance of the pleasure principle in mental life also find expression in the hypothesis that the mental apparatus endeavours to keep the quantity of excitation present in it as low as possible or at least to keep it constant. This latter hypothesis is only another way of stating the pleasure principle; for if the work of the mental apparatus is directed towards keeping the quantity of excitation low, then anything that is calculated to increase that quantity is bound to be felt as adverse to the functioning of the apparatus, that is as unpleasurable. The pleasure principle follows from the principle of constancy: actually the latter principle was inferred from the facts which forced us to adopt the pleasure principle. Moreover, a more detailed discussion will show that the tendency which we thus attribute to the mental apparatus is subsumed as a special case under Fechner's principle of the 'tendency towards stability', to which he has brought the feelings of pleasure and unpleasure into relation.

It must be pointed out, however, that strictly speaking it is incorrect to talk of the dominance of the pleasure principle over the course of mental processes. If such a dominance existed, the immense majority of our mental processes would have to be accompanied by pleasure or to lead to pleasure, whereas universal experience completely contradicts any such conclusion. The most that can be said, therefore, is that there exists in the mind a strong *tendency* towards the pleasure principle, but that that tendency is opposed by certain other forces or circumstances, so that the final outcome cannot always be in harmony with the tendency towards pleasure. We may compare what Fechner (1873, 90) remarks on a similar point: 'Since however a tendency towards an aim does not imply that the aim is attained, and since in general the aim is attainable only by approximations. . . .'

If we turn now to the question of what circumstances are able to prevent the pleasure principle from being carried into effect, we find ourselves once more on secure and well-trodden ground and, in framing our answer, we have at our disposal a rich fund of analytic experience.

The first example of the pleasure principle being inhibited in this way is a familiar one which occurs with regularity. We know that the pleasure principle is proper to a *primary* method of working on the part of the mental apparatus, but that, from the point of view of the self-preservation of the organism among the difficulties of the external world, it is from the very outset inefficient and even highly dangerous. Under the influence of the ego's instincts of self-preservation, the pleasure principle is replaced by the *reality principle*. This latter principle does not abandon the intention of ultimately obtaining pleasure, but it nevertheless demands and carries into effect the postponement of satisfaction, the abandonment of a number of possibilities of gaining satisfaction and the temporary toleration of unpleasure as a step on the long indirect road to pleasure. The pleasure principle long persists, however, as the method of working employed by the sexual instincts, which are so hard to 'educate', and, starting from those instincts, or in the ego itself, it often succeeds in overcoming the reality principle, to the detriment of the organism as a whole.

There can be no doubt, however, that the replacement of the pleasure principle by the reality principle can only be made responsible for a small number, and by no means the most intense, of unpleasurable experiences. Another occasion of the release of unpleasure, which occurs with no less regularity, is to be found in the conflicts and dissensions that take place in the mental apparatus while the ego is passing through its development into more highly composite organizations. Almost all the energy with which the apparatus is filled arises from its innate instinctual impulses. But these are not all allowed to reach the same phases of development. In the course of things it happens again and again that individual instincts or parts of instincts turn out to be incompatible in their aims or demands with the remaining ones, which are able to combine into the inclusive unity of the ego. The former are then split off from this unity by the process of repression, held back at lower levels of psychical development and cut off, to begin with, from the possibility of satisfaction. If they succeed subsequently, as can so easily happen with repressed sexual instincts, in struggling through, by roundabout paths, to a direct or to a substitutive satisfaction, that event, which would in other cases have been an opportunity for pleasure, is felt by the ego as unpleasure. As a consequence of the old conflict which ended in repression, a new breach has occurred in the pleasure principle at the very time when certain instincts were endeavouring, in accordance with the principle, to obtain fresh pleasure. The details of the process by which repression turns a possibility of pleasure into a source of unpleasure are not yet clearly understood or cannot be clearly represented; but there is no doubt that all neurotic unpleasure is of that kind-pleasure that cannot be felt as such.¹

The two sources of unpleasure which I have just indicated are very far from covering the majority of our unpleasurable experiences. But as regards the remainder it can be asserted with some show of justification that their presence does not contradict the dominance of the pleasure principle. Most of the unpleasure that we experience is *perceptual* unpleasure. It may be perception of pressure by unsatisfied instincts; or it may be external perception which is either distressing in itself or which excites unpleasurable expectations in the mental apparatus - that is, which is recognized by it as a 'danger'. The reaction to these instinctual demands, a reaction which constitutes the proper activity of the mental apparatus, can then be directed in a correct manner by the pleasure principle or the reality principle by which the former is modified. This does not seem to necessitate any far-reaching limitation of the pleasure principle. Nevertheless the investigation of the mental reaction to external danger is precisely in a position to produce new material and raise fresh questions bearing upon our present problem.

¹ No doubt the essential point is that pleasure and unpleasure, being conscious feelings, are attached to the ego

II

A condition has long been known and described which occurs after severe mechanical concussions, railway disasters and other accidents involving a risk to life; it has been given the name of 'traumatic neurosis'. The terrible war which has just ended gave rise to a great number of illnesses of this kind, but it at least put an end to the temptation to attribute the cause of the disorder to organic lesions of the nervous system brought about by mechanical force.¹ The symptomatic picture presented by traumatic neurosis approaches that of hysteria in the wealth of its similar motor symptoms, but surpasses it as a rule in its strongly marked signs of subjective ailment (in which it resembles hypochondria or melancholia) as well as in the evidence it gives of a far more comprehensive general enfeeblement and disturbance of the mental capacities. No complete explanation has yet been reached either of war neuroses or of the traumatic neuroses of peace. In the case of the war neuroses, the fact that the same symptoms sometimes came about without the intervention of any gross mechanical force seemed at once enlightening and bewildering. In the case of the ordinary traumatic neuroses two characteristics emerge prominently: first, that the chief weight in their causation seems to rest upon the factor of surprise, of fright; and secondly, that a wound or injury inflicted simultaneously works as a rule *against* the development of a neurosis. 'Fright', 'fear' and 'anxiety' are improperly used as synonymous expressions; they are in fact capable of clear distinction in their relation to danger. 'Anxiety' describes a particular state of expecting the danger or preparing for it, even though it may be an unknown one. 'Fear' requires a definite object of which to be afraid. 'Fright', however, is the name we give to the state a person gets into when he has run into danger without being prepared for it; it emphasizes the factor of surprise. I do not believe anxiety itself can produce a traumatic neurosis. There is something about anxiety that protects its subject against fright and so against fright-neuroses. We shall return to this point later.¹

¹ Cf. the discussion on the psycho-analysis of war neuroses by Freud, Ferenczi, Abraham, Simmel and Jones (1919).

The study of dreams may be considered the most trustworthy method of investigating deep mental processes. Now dreams occurring in traumatic neuroses have the characteristic of repeatedly bringing the patient back into the situation of his accident, a situation from which he wakes up in another fright. This astonishes people far too little. They think the fact that the traumatic experience is constantly forcing itself upon the patient even in his sleep is a proof of the strength of that experience: the patient is, as one might say, fixated to his trauma. Fixations to the experience which started the illness have long been familiar to us in hysteria. Breuer and Freud declared in 1893 that 'hysterics suffer mainly from reminiscences'. In the war neuroses, too, observers like Ferenczi and Simmel have been able to explain certain motor symptoms by fixation to the moment at which the trauma occurred.

I am not aware, however, that patients suffering from traumatic neurosis are much occupied in their waking lives with memories of their accident. Perhaps they are more concerned with *not* thinking of it. Anyone who accepts it as something self-evident that their dreams should put them back at night into the situation that caused them to fall ill has misunderstood the nature of dreams. It would be more in harmony with their nature if they showed the patient pictures from his healthy past or of the cure for which he hopes. If we are not to be shaken in our belief in the wish-fulfilling tenor of dreams by the dreams of traumatic neurotics, we still have one resource open to us: we may argue that the function of dreaming, like so much else, is upset in this condition and diverted from its purposes, or we may be driven to reflect on the mysterious masochistic trends of the ego.

At this point I propose to leave the dark and dismal subject of the traumatic neurosis and pass on to examine the method of working employed by the mental apparatus in one of its earliest *normal* activities - I mean in children's play.

The different theories of children's play have only recently been summarized and discussed from the psycho-analytic point of view by Pfeifer (1919), to whose paper I would refer my readers. These theories attempt to discover the motives which lead children to play, but they fail to bring into the foreground the *economic* motive, the consideration of the yield of pleasure involved. Without wishing to include the whole field covered by these phenomena, I have been able, through a chance opportunity which presented itself, to throw some light upon the first game played by a little boy of one and a half and invented by himself. It was more than a mere fleeting observation, for I lived under the same roof as the child and his parents for some weeks, and it was some time before I discovered the meaning of the puzzling activity which he constantly repeated

The child was not at all precocious in his intellectual development. At the age of one and a half he could say only a few comprehensible words; he could also make use of a number of sounds which expressed a meaning intelligible to those around him. He was, however, on good terms with his parents and their one servant-girl, and tributes were paid to his being a 'good boy'. He did not disturb his parents at night, he conscientiously obeyed orders not to touch certain things or go into certain rooms, and above all he never cried when his mother left him for a few hours. At the same time, he was greatly attached to his mother, who had not only fed him herself but had also looked after him without any outside help. This good little boy, however, had an occasional disturbing habit of taking any small objects he could get hold of and throwing them away from him into a corner, under the bed, and so on, so that hunting for his toys and picking them up was often quite a business. As he did this he gave vent to a loud, long-drawn-out 'o-o-o-o', accompanied by an expression of interest and satisfaction. His mother and the writer of the present account were agreed in thinking that this was not a mere interjection but represented the German word '*fort*'. I eventually realized that it was a game and that the only use he made of any of his toys was to play 'gone' with them. One day I made an observation which confirmed my view. The child had a wooden reel with a piece of string tied round it. It never occurred to him to pull it along the floor behind him, for instance, and play at its being a carriage. What he did was to hold the reel by the string and very skilfully throw it over the edge of his curtained cot, so that it disappeared into it, at the same time uttering his expressive 'o-o-o-o'. He then pulled the reel out of the cot again by the string and hailed its reappearance with a joyful '*da*'. This, then, was the complete game - disappearance and return. As a rule one only witnessed its first act, which was repeated untiringly as a game in itself, though there is no doubt that the greater pleasure was attached to the second act.¹

¹ A further observation subsequently confirmed this interpretation fully. One day the child's mother had been away for several hours and on her return was met with the words 'Baby o-o-o-o!' which was at first incomprehensible. It soon turned out, however, that during this long period of solitude the child had found a method of making *himself* disappear. He had discovered his reflection in a full-length mirror which did not quite reach to the ground, so that by crouching down he could make his mirror-image 'gone'.

The interpretation of the game then became obvious. It was related to the child's great cultural achievement - the instinctual renunciation (that is, the renunciation of instinctual satisfaction) which he had made in allowing his mother to go away without protesting. He compensated himself for this, as it were, by himself staging the disappearance and return of the objects within his reach. It is of course a matter of indifference from the point of view of judging the effective nature of the game whether the child invented it himself or took it over on some outside suggestion. Our interest is directed to another point. The child cannot possibly have felt his mother's departure as something agreeable or even indifferent. How then does his repetition of this distressing experience as a game fit in with the pleasure principle? It may perhaps be said in reply that her departure had to be enacted as a necessary preliminary to her joyful return, and that it was in the latter that lay the true purpose of the game. But against this must be counted the observed fact that the first act, that of departure, was staged as a game in itself and far more frequently than the episode in its entirety, with its pleasurable ending.

No certain decision can be reached from the analysis of a single case like this. On an unprejudiced view one gets an impression that the child turned his experience into a game from another motive. At the outset he was in a *passive* situation - he was overpowered by the experience; but, by repeating it, unpleasurable though it was, as a game, he took on an *active* part. These efforts might be put down to an instinct for mastery that was acting independently of whether the memory was in itself pleasurable or not. But still another interpretation may be attempted. Throwing away the object so that it was 'gone' might satisfy an impulse of the child's, which was suppressed in his actual life, to revenge himself on his mother for going away from him. In that case it would have a defiant meaning: 'All right, then, go away! I don't need you. I'm sending you away myself.' A year later, the same boy whom I had observed at his first game used to take a toy, if he was angry with it, and throw it on the floor, exclaiming: 'Go to the front!' He had heard at that time that his absent father was 'at the front', and was far from regretting his absence; on the contrary he made it quite clear that he had no desire to be disturbed in his sole possession of his mother.¹ We know of other children who liked to express similar hostile impulses by throwing away objects instead of persons.² We are therefore left in doubt as to whether the impulse to work over in the mind some overpowering experience so as to make oneself master of it can find expression as a primary event, and independently of the pleasure principle. For, in the case we have been discussing, the child may, after all, only have been able to repeat his unpleasant experience in play because the repetition carried along with it a yield of pleasure of another sort but none the less a direct one.

¹ When this child was five and three-quarters, his mother died. Now that she was really 'gone' ('o-o-o'), the little boy showed no signs of grief. It is true that in the interval a second child had been born and had roused him to violent jealousy.

² Cf. my note on a childhood memory of Goethe's (1917*b*).

Nor shall we be helped in our hesitation between these two views by further considering children's play. It is clear that in their play children repeat everything that has made a great impression on them in real life, and that in doing so they abreact the strength of the impression and, as one might put it, make themselves master of the situation. But on the other hand it is obvious that all their play is influenced by a wish that dominates them the whole time - the wish to be grown-up and to be able to do what grown-up people do. It can also be observed that the unpleasurable nature of an experience does not always unsuit it for play. If the doctor looks down a child's throat or carries out some small operation on him, we may be quite sure that these frightening experiences will be the subject of the next game; but we must not in that connection overlook the fact that there is a yield of pleasure from another source. As the child passes over from the passivity of the experience to the activity of the game, he hands on the disagreeable experience to one of his playmates and in this way revenges himself on a substitute.

Nevertheless, it emerges from this discussion that there is no need to assume the existence of a special imitative instinct in order to provide a motive for play. Finally, a reminder may be added that the artistic play and artistic imitation carried out by adults, which, unlike children's, are aimed at an audience, do not spare the spectators (for instance, in tragedy) the most painful experiences and can yet be felt by them as highly enjoyable. This is convincing proof that, even under the dominance of the pleasure principle, there are ways and means enough of making what is in itself unpleasurable into a subject to be recollected and worked over in the mind. The consideration of these cases and situations, which have a yield of pleasure as their final outcome, should be undertaken by some system of aesthetics with an economic approach to its subject-matter. They are of no use for *our* purposes, since they presuppose the existence and dominance of the pleasure principle; they give no evidence of the operation of tendencies *beyond* the pleasure principle, that is, of tendencies more primitive than it and independent of it.

III

Twenty five years of intense work have had as their result that the immediate aims of psycho-analytic technique are quite other to-day than they were at the outset. At first the analysing physician could do no more than discover the unconscious material that was concealed from the patient, put it together, and, at the right moment, communicate it to him. Psychoanalysis was then first and foremost an art of interpreting. Since this did not solve the therapeutic problem, a further aim quickly came in view: to oblige the patient to confirm the analyst's construction from his own memory. In that endeavour the chief emphasis lay upon the patient's resistances: the art consisted now in uncovering these as quickly as possible, in pointing them out to the patient and in inducing him by human influence - this was where suggestion operating as 'transference' played its part - to abandon his resistances.

But it became ever clearer that the aim which had been set up - the aim that what was unconscious should become conscious - is not completely attainable by that method. The patient cannot remember the whole of what is repressed in him, and what he cannot remember may be precisely the essential part of it. Thus he acquires no sense of conviction of the correctness of the construction that has been communicated to him. He is obliged to *repeat* the repressed material as a contemporary experience instead of, as the physician would prefer to see, *remembering* it as something belonging to the past.¹ These reproductions, which emerge with such unwished-for exactitude, always have as their subject some portion of infantile sexual life - of the Oedipus complex, that is, and its derivatives; and they are invariably acted out in the sphere of the transference, of the patient's relation to the physician. When things have reached this stage, it may be said that the earlier neurosis has now been replaced by a fresh, 'transference neurosis'. It has been the physician's endeavour to keep this transference neurosis within the narrowest limits: to force as much as possible into the channel of memory and to allow as little as possible to emerge as repetition. The ratio between what is remembered and what is reproduced varies from case to case. The physician cannot as a rule spare his patient this phase of the treatment. He must get him to re-experience some portion of his forgotten life, but must see to it, on the other hand, that the patient retains some degree of aloofness, which will enable him, in spite of everything, to recognize that what appears to be reality is in fact only a reflection of a forgotten past. If this can be successfully achieved, the patient's sense of conviction is won, together with the therapeutic success that is dependent on it.

¹ See my paper on 'Recollecting, Repeating and Working Through' (1914g).

In order to make it easier to understand this 'compulsion to repeat', which emerges during the psycho-analytic treatment of neurotics, we must above all get rid of the mistaken notion that what we are dealing with in our struggle against resistances is resistance on the part of the *unconscious*. The unconscious - that is to say, the 'repressed' - offers no resistance whatever to the efforts of the treatment. Indeed, it itself has no other endeavour than to break through the pressure weighing down on it and force its way either to consciousness or to a discharge through some real action. Resistance during treatment arises from the same higher strata and systems of the mind which originally carried out repression. But the fact that, as we know from experience, the motives of the resistances, and indeed the resistances themselves, are unconscious at first during the treatment, is a hint to us that we should correct a shortcoming in our terminology. We shall avoid a lack of clarity if we make our contrast not between the conscious and the unconscious but between the coherent *ego* and the *repressed*. It is certain that much of the ego is itself unconscious, and notably what we may describe as its nucleus; only a small part of it is covered by the term 'preconscious'. Having replaced a purely descriptive terminology by one which is systematic or dynamic, we can say that the patient's resistance arises from his ego, and we then at once perceive that the compulsion to repeat must be ascribed to the unconscious repressed. It seems probable that the compulsion can only express itself after the work of treatment has gone half-way to meet it and has loosened the repression.¹

¹ I have argued elsewhere that what thus comes to the help of the compulsion to repeat is the factor of 'suggestion' in the treatment - that is, the patient's submissiveness to the physician, which has its roots deep in his unconscious parental complex.

There is no doubt that the resistance of the conscious and unconscious ego operates under the sway of the pleasure principle: it seeks to avoid the unpleasure which would be produced by the liberation of the repressed. *Our* efforts, on the other hand, are directed towards procuring the toleration of that unpleasure by an appeal to the reality principle. But how is the compulsion to repeat - the manifestation of the power of the repressed - related to the pleasure principle? It is clear that the greater part of what is re-experienced under the compulsion to repeat must cause the ego unpleasure, since it brings to light activities of repressed instinctual impulses. That, however, is unpleasure of a kind we have already considered and does not contradict the pleasure principle: unpleasure for one system and simultaneously satisfaction for the other. But we come now to a new and remarkable fact, namely that the compulsion to repeat also recalls from the past experiences which include no possibility of pleasure, and which can never, even long ago, have brought satisfaction even to instinctual impulses which have since been repressed.

The early efflorescence of infantile sexual life is doomed to extinction because its wishes are incompatible with reality and with the inadequate stage of development which the child has reached. That efflorescence comes to an end in the most distressing circumstances and to the accompaniment of the most painful feelings. Loss of love and failure leave behind them a permanent injury to self-regard in the form of a narcissistic scar, which in my opinion, as well as in Marciniowski's (1918), contributes more than anything to the 'sense of inferiority' which is so common in neurotics. The child's sexual researches, on which limits are imposed by his physical development, lead to no satisfactory conclusion; hence such later complaints as 'I can't accomplish anything; I can't succeed in anything'. The tie of affection, which binds the child as a rule to the parent of the opposite sex, succumbs to disappointment, to a vain expectation of satisfaction or to jealousy over the birth of a new baby - unmistakable proof of the infidelity of the object of the child's affections. His own attempt to make a baby himself, carried out with tragic seriousness, fails shamefully. The lessening amount of affection he receives, the increasing demands of education, hard words and an occasional punishment - these show him at last the full extent to which he has been scorned. These are a few typical and constantly recurring instances of the ways in which the love characteristic of the age of childhood is brought to a conclusion.

Patients repeat all of these unwanted situations and painful emotions in the transference and revive them with the greatest ingenuity. They seek to bring about the interruption of the treatment while it is still incomplete; they contrive once more to feel themselves scorned, to oblige the physician to speak severely to them and treat them coldly; they discover appropriate objects for their jealousy; instead of the passionately desired baby of their childhood, they produce a plan or a promise of some grand present - which turns out as a rule to be no less unreal. None of these things can have produced pleasure in the past, and it might be supposed that they would cause less unpleasure to-day if they emerged as memories or dreams instead of taking the form of fresh experiences. They are of course the activities of instincts intended to lead to satisfaction; but no lesson has been learnt from the old experience of these activities having led instead only to unpleasure. In spite of that, they are repeated, under pressure of a compulsion.

What psycho-analysis reveals in the transference phenomena of neurotics can also be observed in the lives of some normal people. The impression they give is of being pursued by a malignant fate or possessed by some 'daemonic' power; but psycho-analysis has always taken the view that their fate is for the most part arranged by themselves and determined by early infantile influences. The compulsion which is here in evidence differs in no way from the compulsion to repeat which we have found in neurotics, even though the people we are now considering have never shown any signs of dealing with a neurotic conflict by producing symptoms. Thus we have come across people all of whose human relationships have the same outcome: such as the benefactor who is abandoned in anger after a time by each of his *protégés*, however much they may otherwise differ from one another, and who thus seems doomed to taste all the bitterness of ingratitude; or the man whose friendships all end in betrayal by his friend; or the man who time after time in the course of his life raises someone else into a position of great private or public authority and then, after a certain interval, himself upsets that authority and replaces him by a new one; or, again, the lover each of whose love affairs with a woman passes through the same phases and reaches the same conclusion. This 'perpetual recurrence of the same thing' causes us no astonishment when it relates to *active* behaviour on the part of the person concerned and when we can discern in him an essential character-trait which always remains the same and which is compelled to find expression in a repetition of the same experiences. We are much more impressed by cases where the subject appears to have a *passive* experience, over which he has no influence, but in which he meets with a repetition of the same fatality. There is the case, for instance, of the woman who married three successive husbands each of whom fell ill soon afterwards and had to be nursed by her on their death-beds.¹ The most moving poetic picture of a fate such as this is given by Tasso in his romantic epic *Gerusalemme Liberata*. Its hero, Tancred, unwittingly kills his beloved Clorinda in a duel while she is disguised in the armour of an enemy knight. After her burial he makes his way into a strange magic forest which strikes the Crusaders' army with terror. He slashes with his sword at a tall tree; but blood streams from the cut and the voice of Clorinda, whose soul is imprisoned in the tree, is heard complaining that he has wounded his beloved once again.

If we take into account observations such as these, based upon behaviour in the transference and upon the life-histories of men and women, we shall find courage to assume that there really does exist in the mind a compulsion to repeat which overrides the pleasure principle. Now too we shall be inclined to relate to this compulsion the dreams which occur in traumatic neuroses and the impulse which leads children to play.

¹ Cf. the apt remarks on this subject by C. G. Jung (1909).

But it is to be noted that only in rare instances can we observe the pure effects of the compulsion to repeat, unsupported by other motives. In the case of children's play we have already laid stress on the other ways in which the emergence of the compulsion may be interpreted; the compulsion to repeat and instinctual satisfaction which is immediately pleasurable seem to converge here into an intimate partnership. The phenomena of transference are obviously exploited by the resistance which the ego maintains in its pertinacious insistence upon repression; the compulsion to repeat, which the treatment tries to bring into its service is, as it were, drawn over by the ego to *its* side (clinging as the ego does to the pleasure principle). A great deal of what might be described as the compulsion of destiny seems intelligible on a rational basis; so that we are under no necessity to call in a new and mysterious motive force to explain it.

The least dubious instance is perhaps that of traumatic dreams. But on maturer reflection we shall be forced to admit that even in the other instances the whole ground is not covered by the operation of the familiar motive forces. Enough is left unexplained to justify the hypothesis of a compulsion to repeat - something that seems more primitive, more elementary, more instinctual than the pleasure principle which it overrides. But if a compulsion to repeat *does* operate in the mind, we should be glad to know something about it, to learn what function it corresponds to, under what conditions it can emerge and what its relation is to the pleasure principle - to which, after all, we have hitherto ascribed dominance over the course of the processes of excitation in mental life.

IV

What follows is speculation, often far-fetched speculation, which the reader will consider or dismiss according to his individual predilection. It is further an attempt to follow out an idea consistently, out of curiosity to see where it will lead.

Psycho-analytic speculation takes as its point of departure the impression, derived from examining unconscious processes, that consciousness may be, not the most universal attribute of mental processes, but only a particular function of them. Speaking in metapsychological terms, it asserts that consciousness is a function of a particular system which it describes as *Cs.* What consciousness yields consists essentially of perceptions of excitations coming from the external world and of feelings of pleasure and unpleasure which can only arise from within the mental apparatus; it is therefore possible to assign to the system *Pcpt.-Cs.* a position in space. It must lie on the borderline between outside and inside; it must be turned towards the external world and must envelop the other psychical systems. It will be seen that there is nothing daringly new in these assumptions; we have merely adopted the views on localization held by cerebral anatomy, which locates the 'seat' of consciousness in the cerebral cortex - the outermost, enveloping layer of the central organ. Cerebral anatomy has no need to consider why, speaking anatomically, consciousness should be lodged on the surface of the brain instead of being safely housed somewhere in its inmost interior. Perhaps we shall be more successful in accounting for this situation in the case of our system *Pcpt.-Cs.*

Consciousness is not the only distinctive character which we ascribe to the processes in that system. On the basis of impressions derived from our psycho-analytic experience, we assume that all excitatory processes that occur in the *other* systems leave permanent traces behind in them which form the foundation of memory. Such memory-traces, then, have nothing to do with the fact of becoming conscious; indeed they are often most powerful and most enduring when the process which left them behind was one which never entered consciousness. We find it hard to believe, however, that permanent traces of excitation such as these are also left in the system *Pcpt.-Cs.* If they remained constantly conscious, they would very soon set limits to the system's aptitude for receiving fresh excitations.¹ If, on the other hand, they were unconscious, we should be faced with the problem of explaining the existence of unconscious processes in a system whose functioning was otherwise accompanied by the phenomenon of consciousness. We should, so to say, have altered nothing and gained nothing by our hypothesis relegating the process of becoming conscious to a special system. Though this consideration is not absolutely conclusive, it nevertheless leads us to suspect that becoming conscious and leaving behind a memory-trace are processes incompatible with each other within one and the same system. Thus we should be able to say that the excitatory process becomes conscious in the system *Cs.* but leaves no permanent trace behind there; but that the excitation is transmitted to the systems lying next within and that it is in *them* that its traces are left. I followed these same lines in the schematic picture which I included in the speculative section of my *Interpretation of Dreams*. It must be borne in mind that little enough is known from other sources of the origin of consciousness; when, therefore, we lay down the proposition that *consciousness arises instead of a memory-trace*, the assertion deserves consideration, at all events on the ground of its being framed in fairly precise terms.

If this is so, then, the system *Cs.* is characterized by the peculiarity that in it (in contrast to what happens in the other psychical systems) excitatory processes do not leave behind any permanent change in its elements but expire, as it were, in the phenomenon of becoming conscious. An exception of this sort to the general rule requires to be explained by some factor that applies exclusively to that one system. Such a factor, which is absent in the other systems, might well be the exposed situation of the system *Cs.*, immediately abutting as it does on the external world.

¹ What follows is based throughout on Breuer's views in *Studies on Hysteria* (Breuer and Freud, 1895).

Let us picture a living organism in its most simplified possible form as an undifferentiated vesicle of a substance that is susceptible to stimulation. Then the surface turned towards the external world will from its very situation be differentiated and will serve as an organ for receiving stimuli. Indeed embryology, in its capacity as a recapitulation of developmental history, actually shows us that the central nervous system originates from the ectoderm; the grey matter of the cortex remains a derivative of the primitive superficial layer of the organism and may have inherited some of its essential properties. It would be easy to suppose, then, that as a result of the ceaseless impact of external stimuli on the surface of the vesicle, its substance to a certain depth may have become permanently modified, so that excitatory processes run a different course in it from what they run in the deeper layers. A crust would thus be formed which would at last have been so thoroughly 'baked through' by stimulation that it would present the most favourable possible conditions for the reception of stimuli and become incapable of any further modification. In terms of the system Cs., this would mean that its elements could undergo no further permanent modification from the passage of excitation, because they had already been modified in the respect in question to the greatest possible extent: now, however, they would have become capable of giving rise to consciousness. Various ideas may be formed which cannot at present be verified as to the nature of this modification of the substance and of the excitatory process. It may be supposed that, in passing from one element to another, an excitation has to overcome a resistance, and that the diminution of resistance thus effected is what lays down a permanent trace of the excitation, that is, a facilitation. In the system Cs., then, resistance of this kind to passage from one element to another would no longer exist. This picture can be brought into relation with Breuer's distinction between quiescent (or bound) and mobile cathectic energy in the elements of the psychical systems;¹ the elements of the system Cs. would carry no bound energy but only energy capable of free discharge. It seems best, however, to express oneself as cautiously as possible on these points. None the less, this speculation will have enabled us to bring the origin of consciousness into some sort of connection with the situation of the system Cs. and with the peculiarities that must be ascribed to the excitatory processes taking place in it.

¹ Breuer and Freud, 1895.

But we have more to say of the living vesicle with its receptive cortical layer. This little fragment of living substance is suspended in the middle of an external world charged with the most powerful energies; and it would be killed by the stimulation emanating from these if it were not provided with a protective shield against stimuli. It acquires the shield in this way: its outermost surface ceases to have the structure proper to living matter, becomes to some degree inorganic and thenceforward functions as a special envelope or membrane resistant to stimuli. In consequence, the energies of the external world are able to pass into the next underlying layers, which have remained living, with only a fragment of their original intensity; and these layers can devote themselves, behind the protective shield, to the reception of the amounts of stimulus which have been allowed through it. By its death, the outer layer has saved all the deeper ones from a similar fate - unless, that is to say, stimuli reach it which are so strong that they break through the protective shield. *Protection against* stimuli is an almost more important function for the living organism than *reception of* stimuli. The protective shield is supplied with its own store of energy and must above all endeavour to preserve the special modes of transformation of energy operating in it against the effects threatened by the enormous energies at work in the external world - effects which tend towards a levelling out of them and hence towards destruction. The main purpose of the *reception* of stimuli is to discover the direction and nature of the external stimuli; and for that it is enough to take small specimens of the external world, to sample it in small quantities. In highly developed organisms the receptive cortical layer of the former vesicle has long been withdrawn into the depths of the interior of the body, though portions of it have been left behind on the surface immediately beneath the general shield against stimuli. These are the sense organs, which consist essentially of apparatus for the reception of certain specific effects of stimulation, but which also include special arrangements for further protection against excessive amounts of stimulation and for excluding unsuitable kinds of stimuli. It is characteristic of them that they deal only with very small quantities of external stimulation and only take in *samples* of the external world. They may perhaps be compared with feelers which are all the time making tentative advances towards the external world and then drawing back from it.

At this point I shall venture to touch for a moment upon a subject which would merit the most exhaustive treatment. As a result of certain psycho-analytic discoveries, we are to-day in a position to embark on a discussion of the Kantian theorem that time and space are 'necessary forms of thought'. We have learnt that unconscious mental processes are in themselves 'timeless'. This means in the first place that they are not ordered temporally, that time does not change them in any way and that the idea of time cannot be applied to them. These are negative characteristics which can only be clearly understood if a comparison is made with *conscious* mental processes. On the other hand, our abstract idea of time seems to be wholly derived from the method of working of the system *Pcpt.*-Cs. and to correspond to a perception on its own part of that method of working. This mode of functioning may perhaps constitute another way of providing a shield against stimuli. I know that these remarks must sound very obscure, but I must limit myself to these hints.

We have pointed out how the living vesicle is provided with a shield against stimuli from the external world; and we had previously shown that the cortical layer next to that shield must be differentiated as an organ for receiving stimuli from without. This sensitive cortex, however, which is later to become the system Cs., also receives excitations from *within*. The situation of the system between the outside and the inside and the difference between the conditions governing the reception of excitations in the two cases have a decisive effect on the functioning of the system and of the whole mental apparatus. Towards the outside it is shielded against stimuli, and the amounts of excitation impinging on it have only a reduced effect. Towards the inside there can be no such shield; the excitations in the deeper layers extend into the system directly and in undiminished amount, in so far as certain of their characteristics give rise to feelings in the pleasure-unpleasure series. The excitations coming from within are, however, in their intensity and in other, qualitative, respects - in their amplitude, perhaps - more commensurate with the system's method of working than the stimuli which stream in from the external world. This state of things produces two definite results. First, the feelings of pleasure and unpleasure (which are an index to what is happening in the interior of the apparatus) predominate over all external stimuli. And secondly, a particular way is adopted of dealing with any internal excitations which produce too great an increase of unpleasure: there is a tendency to treat them as though they were acting, not from the inside, but from the outside, so that it may be possible to bring the shield against stimuli into operation as a means of defence against them. This is the origin of *projection*, which is destined to play such a large part in the causation of pathological processes.

I have an impression that these last considerations have brought us to a better understanding of the dominance of the pleasure principle; but no light has yet been thrown on the cases that contradict that dominance. Let us therefore go a step further. We describe as 'traumatic' any excitations from outside which are powerful enough to break through the protective shield. It seems to me that the concept of trauma necessarily implies a connection of this kind with a breach in an otherwise efficacious barrier against stimuli. Such an event as an external trauma is bound to provoke a disturbance on a large scale in the functioning of the organism's energy and to set in motion every possible defensive measure. At the same time, the pleasure principle is for the moment put out of action. There is no longer any possibility of preventing the mental apparatus from being flooded with large amounts of stimulus, and another problem arises instead - the problem of mastering the amounts of stimulus which have broken in and of binding them, in the psychical sense, so that they can then be disposed of.

The specific unpleasure of physical pain is probably the result of the protective shield having been broken through in a limited area. There is then a continuous stream of excitations from the part of the periphery concerned to the central apparatus of the mind, such as could normally arise only from *within* the apparatus. And how shall we expect the mind to react to this invasion? Cathectic energy is summoned from all sides to provide sufficiently high cathexes of energy in the environs of the breach. An 'anticathexis' on a grand scale is set up, for whose benefit all the other psychical systems are impoverished, so that the remaining psychical functions are extensively paralysed or reduced. We must endeavour to draw a lesson from examples such as this and use them as a basis for our metapsychological speculations. From the present case, then, we infer that a system which is itself highly cathected is capable of taking up an additional stream of fresh inflowing energy and of converting it into quiescent cathexis, that is of binding it psychically. The higher the system's own quiescent cathexis, the greater seems to be its binding force; conversely, therefore, the lower its cathexis, the less capacity will it have for taking up inflowing energy and the more violent must be the consequences of such a breach in the protective shield against stimuli. To this view it cannot be justly objected that the increase of cathexis round the breach can be explained far more simply as the direct result of the inflowing masses of excitation. If that were so, the mental apparatus would merely receive an increase in its cathexes of energy, and the paralysing character of pain and the impoverishment of all the other systems would remain unexplained. Nor do the very violent phenomena of discharge to which pain gives rise affect our explanation, for they occur in a reflex manner - that is, they follow without the intervention of the mental apparatus. The indefiniteness of all our discussions on what we describe as metapsychology is of course due to the fact that we know nothing of the nature of the excitatory process that takes place in the elements of the psychical systems, and that we do not feel justified in framing any hypothesis on the subject. We are consequently operating all the time with a large unknown factor, which we are obliged to carry over into every new formula. It may be reasonably supposed that this excitatory process can be carried out with energies that vary *quantitatively*; it may also seem probable that it has more than one *quality* (in the nature of amplitude, for instance). As a new factor we have taken into consideration Breuer's hypothesis that charges of energy occur in two forms; so that we have to distinguish between two kinds of cathexis of the psychical systems or their elements - a freely flowing cathexis that presses on towards discharge and a quiescent cathexis. We may perhaps suspect that the binding of the energy that streams into the mental apparatus consists in its change from a freely flowing into a quiescent state.

We may, I think, tentatively venture to regard the common traumatic neurosis as a consequence of an extensive breach being made in the protective shield against stimuli. This would seem to reinstate the old, naïve theory of shock, in apparent contrast to the later and psychologically more ambitious theory which attributes aetiological importance not to the effects of mechanical violence but to fright and the threat to life. These opposing views are not, however, irreconcilable; nor is the psycho-analytic view of the traumatic neurosis identical with the shock theory in its crudest form. The latter regards the essence of the shock as being the direct damage to the molecular structure or even to the histological structure of the elements of the nervous system; whereas what we seek to understand are the effects produced on the organ of the mind by the breach in the shield against stimuli and by the problems that follow in its train. And we still attribute importance to the element of fright. It is caused by lack of any preparedness for anxiety, including lack of hypercathexis of the systems that would be the first to receive the stimulus. Owing to their low cathexis those systems are not in a good position for binding the inflowing amounts of excitation and the consequences of the breach in the protective shield follow all the more easily. It will be seen, then, that preparedness for anxiety and the hypercathexis of the receptive systems constitute the last line of defence of the shield against stimuli. In the case of quite a number of traumas, the difference between systems that are unprepared and systems that are well prepared through being hypercathected may be a decisive factor in determining the outcome; though where the strength of a trauma exceeds a certain limit this factor will no doubt cease to carry weight. The fulfilment of wishes is, as we know, brought about in a hallucinatory manner by dreams, and under the dominance of the pleasure principle this has become their function. But it is not in the service of that principle that the dreams of patients suffering from traumatic neuroses lead them back with such regularity to the situation in which the trauma occurred. We may assume, rather, that dreams are here helping to carry out another task, which must be accomplished before the dominance of the pleasure principle can ever begin. These dreams are endeavouring to master the stimulus retrospectively, by developing the anxiety whose omission was the cause of the traumatic neurosis. They thus afford us a view of a function of the mental apparatus which, though it does not contradict the pleasure principle, is nevertheless independent of it and seems to be more primitive than the purpose of gaining pleasure and avoiding unpleasure.

This would seem to be the place, then, at which to admit for the first time an exception to the proposition that dreams are fulfilments of wishes. Anxiety dreams, as I have shown repeatedly and in detail, offer no such exception. Nor do 'punishment dreams', for they merely replace the forbidden wish-fulfilment by the appropriate punishment for it; that is to say, they fulfil the wish of the sense of guilt which is the reaction to the repudiated impulse. But it is impossible to classify as wish-fulfilments the dreams we have been discussing which occur in traumatic neuroses, or the dreams during psycho-analyses which bring to memory the psychical traumas of childhood. They arise, rather, in obedience to the compulsion to repeat, though it is true that in analysis that compulsion is supported by the wish (which is encouraged by 'suggestion') to conjure up what has been forgotten and repressed. Thus it would seem that the function of dreams, which consists in setting aside any motives that might interrupt sleep, by fulfilling the wishes of the disturbing impulses, is not their *original* function. It would not be possible for them to perform that function until the whole of mental life had accepted the dominance of the pleasure principle. If there is a 'beyond the pleasure principle', it is only consistent to grant that there was also a time before the purpose of dreams was the fulfilment of wishes. This would imply no denial of their later function. But if once this general rule has been broken, a further question arises. May not dreams which, with a view to the psychical binding of traumatic impressions, obey the compulsion to repeat - may not such dreams occur *outside* analysis as well? And the reply can only be a decided affirmative.

I have argued elsewhere¹ that 'war neuroses' (in so far as that term implies something more than a reference to the circumstances of the illness's onset) may very well be traumatic neuroses which have been facilitated by a conflict in the ego. The fact to which I have referred in the first paragraph of Chapter II, that a gross physical injury caused simultaneously by the trauma diminishes the chances that a neurosis will develop, becomes intelligible if one bears in mind two facts which have been stressed by psycho-analytic research: firstly, that mechanical agitation must be recognized as one of the sources of sexual excitation,² and secondly, that painful and feverish illnesses exercise a powerful effect, so long as they last, on the distribution of libido. Thus, on the one hand, the mechanical violence of the trauma would liberate a quantity of sexual excitation which, owing to the lack of preparation for anxiety, would have a traumatic effect; but, on the other hand, the simultaneous physical injury, by calling for a narcissistic hypercathexis of the injured organ,³ would bind the excess of excitation. It is also well known, though the libido theory has not yet made sufficient use of the fact, that such severe disorders in the distribution of libido as melancholia are temporarily brought to an end by intercurrent organic illness, and indeed that even a fully developed condition of dementia praecox is capable of a temporary remission in these same circumstances.

¹ See my introduction (1919d) to *Psycho-analysis and the War Neuroses*.

³ See my paper on narcissism (1914c).

V

The fact that the cortical layer which receives stimuli is without any protective shield against excitations from within must have as its result that these latter transmissions of stimulus have a preponderance in economic importance and often occasion economic disturbances comparable with traumatic neuroses. The most abundant sources of this internal excitation are what are described as the organism's 'instincts' - the representatives of all the forces originating in the interior of the body and transmitted to the mental apparatus - at once the most important and the most obscure element of psychological research.

It will perhaps not be thought too rash to suppose that the impulses arising from the instincts do not belong to the type of *bound* nervous processes but of *freely mobile* processes which press towards discharge. The best part of what we know of these processes is derived from our study of the dream-work. We there discovered that the processes in the unconscious systems were fundamentally different from those in the preconscious (or conscious) systems. In the unconscious, cathexes can easily be completely transferred, displaced and condensed. Such treatment, however, could produce only invalid results if it were applied to preconscious material; and this accounts for the familiar peculiarities exhibited by manifest dreams after the preconscious residues of the preceding day have been worked over in accordance with the laws operating in the unconscious. I described the type of process found in the unconscious as the 'primary' psychical process, in contradistinction to the 'secondary' process which is the one obtaining in our normal waking life. Since all instinctual impulses have the unconscious systems as their point of impact, it is hardly an innovation to say that they obey the primary process. Again, it is easy to identify the primary psychical process with Breuer's freely mobile cathexis and the secondary process with changes in his bound or tonic cathexis.¹ If so, it would be the task of the higher strata of the mental apparatus to bind the instinctual excitation reaching the primary process. A failure to effect this binding would provoke a disturbance analogous to a traumatic neurosis; and only after the binding has been accomplished would it be possible for the dominance of the pleasure principle (and of its modification, the reality principle) to proceed unhindered. Till then the other task of the mental apparatus, the task of mastering or binding excitations, would have precedence - not, indeed, in *opposition* to the pleasure principle, but independently of it and to some extent in disregard of it.

¹ Cf. my *Interpretation of Dreams*, Chapter VII.

The manifestations of a compulsion to repeat (which we have described as occurring in the early activities of infantile mental life as well as among the events of psycho-analytic treatment) exhibit to a high degree an instinctual character and, when they act in opposition to the pleasure principle, give the appearance of some 'daemonic' force at work. In the case of children's play we seemed to see that children repeat unpleasurable experiences for the additional reason that they can master a powerful impression far more thoroughly by being active than they could by merely experiencing it passively. Each fresh repetition seems to strengthen the mastery they are in search of. Nor can children have their *pleasurable* experiences repeated often enough, and they are inexorable in their insistence that the repetition shall be an identical one. This character trait disappears later on. If a joke is heard for a second time it produces almost no effect; a theatrical production never creates so great an impression the second time as the first; indeed, it is hardly possible to persuade an adult who has very much enjoyed reading a book to re-read it immediately. Novelty is always the condition of enjoyment. But children will never tire of asking an adult to repeat a game that he has shown them or played with them, till he is too exhausted to go on. And if a child has been told a nice story, he will insist on hearing it over and over again rather than a new one; and he will remorselessly stipulate that the repetition shall be an identical one and will correct any alterations of which the narrator may be guilty - though they may actually have been made in the hope of gaining fresh approval. None of this contradicts the pleasure principle; repetition, the re-experiencing of something identical, is clearly in itself a source of pleasure. In the case of a person in analysis, on the contrary, the compulsion to repeat the events of his childhood in the transference evidently disregards the pleasure principle in every way. The patient behaves in a purely infantile fashion and thus shows us that the repressed memory-traces of his *primaevae* experiences are not present in him in a bound state and are indeed in a sense incapable of obeying the secondary process. It is to this fact of not being bound, moreover, that they owe their capacity for forming, in conjunction with the residues of the previous day, a wishful phantasy that emerges in a dream. This same compulsion to repeat frequently meets us as an obstacle to our treatment when at the end of an analysis we try to induce the patient to detach himself completely from his physician. It may be presumed, too, that when people unfamiliar with analysis feel an obscure fear - a dread of rousing something that, so they feel, is better left sleeping - what they are afraid of at bottom is the emergence of this compulsion with its hint of possession by some 'daemonic' power.

But how is the predicate of being 'instinctual' related to the compulsion to repeat? At this point we cannot escape a suspicion that we may have come upon the track of a universal attribute of instincts and perhaps of organic life in general which has not hitherto been clearly recognized or at least not explicitly stressed. *It seems, then, that an instinct is an urge inherent in organic life to restore an earlier state of things* which the living entity has been obliged to abandon under the pressure of external disturbing forces; that is, it is a kind of organic elasticity, or, to put it another way, the expression of the inertia inherent in organic life.¹

¹ I have no doubt that similar notions as to the nature of 'instincts' have already been put forward repeatedly.

This view of instincts strikes us as strange because we have become used to see in them a factor impelling towards change and development, whereas we are now asked to recognize in them the precise contrary - an expression of the *conservative* nature of living substance. On the other hand we soon call to mind examples from animal life which seem to confirm the view that instincts are historically determined. Certain fishes, for instance, undertake laborious migrations at spawning-time in order to deposit their spawn in particular waters far removed from their customary haunts. In the opinion of many biologists what they are doing is merely to seek out the localities in which their species formerly resided but which in the course of time they have exchanged for others. The same explanation is believed to apply to the migratory flights of birds of passage - but we are quickly relieved of the necessity for seeking for further examples by the reflection that the most impressive proofs of there being an organic compulsion to repeat lie in the phenomena of heredity and the facts of embryology. We see how the germ of a living animal is obliged in the course of its development to recapitulate (even if only in a transient and abbreviated fashion) the structures of all the forms from which it is sprung, instead of proceeding quickly by the shortest path to its final shape. This behaviour is only to a very slight degree attributable to mechanical causes, and the historical explanation cannot accordingly be neglected. So too the power of regenerating a lost organ by growing afresh a precisely similar one extends far up into the animal kingdom.

We shall be met by the plausible objection that it may very well be that, in addition to the conservative instincts which impel towards repetition, there may be others which push forward towards progress and the production of new forms. This argument must certainly not be overlooked, and it will be taken into account at a later stage. But for the moment it is tempting to pursue to its logical conclusion the hypothesis that all instincts tend towards the restoration of an earlier state of things. The outcome may give an impression of mysticism or of sham profundity; but we can feel quite innocent of having had any such purpose in view. We seek only for the sober results of research or of reflection based on it; and we have no wish to find in those results any quality other than certainty.¹

¹ The reader should not overlook the fact that what follows is the development of an extreme line of thought. Later on, when account is taken of the sexual instincts, it will be found that the necessary limitations and corrections are applied to it.

Let us suppose, then, that all the organic instincts are conservative, are acquired historically and tend towards the restoration of an earlier state of things. It follows that the phenomena of organic development must be attributed to external disturbing and diverting influences. The elementary living entity would from its very beginning have had no wish to change; if conditions remained the same, it would do no more than constantly repeat the same course of life. In the last resort, what has left its mark on the development of organisms must be the history of the earth we live in and of its relation to the sun. Every modification which is thus imposed upon the course of the organism's life is accepted by the conservative organic instincts and stored up for further repetition. Those instincts are therefore bound to give a deceptive appearance of being forces tending towards change and progress, whilst in fact they are merely seeking to reach an ancient goal by paths alike old and new. Moreover it is possible to specify this final goal of all organic striving. It would be in contradiction to the conservative nature of the instincts if the goal of life were a state of things which had never yet been attained. On the contrary, it must be an *old* state of things, an initial state from which the living entity has at one time or other departed and to which it is striving to return by the circuitous paths along which its development leads. If we are to take it as a truth that knows no exception that everything living dies for *internal* reasons - becomes inorganic once again - then we shall be compelled to say that '*the aim of life is death*' and, looking backwards, that '*inanimate things existed before living ones*'.

The attributes of life were at some time evoked in inanimate matter by the action of a force of whose nature we can form no conception. It may perhaps have been a process similar in type to that which later caused the development of consciousness in a particular stratum of living matter. The tension which then arose in what had hitherto been an inanimate substance endeavoured to cancel itself out. In this way the first instinct came into being: the instinct to return to the inanimate state. It was still an easy matter at that time for a living substance to die; the course of its life was probably only a brief one, whose direction was determined by the chemical structure of the young life. For a long time, perhaps, living substance was thus being constantly created afresh and easily dying, till decisive external influences altered in such a way as to oblige the still surviving substance to diverge ever more widely from its original course of life and to make ever more complicated *détours* before reaching its aim of death. These circuitous paths to death, faithfully kept to by the conservative instincts, would thus present us to-day with the picture of the phenomena of life. If we firmly maintain the exclusively conservative nature of instincts, we cannot arrive at any other notions as to the origin and aim of life.

The implications in regard to the great groups of instincts which, as we believe, lie behind the phenomena of life in organisms must appear no less bewildering. The hypothesis of self-preservative instincts, such as we attribute to all living beings, stands in marked opposition to the idea that instinctual life as a whole serves to bring about death. Seen in this light, the theoretical importance of the instincts of self-preservation, of self-assertion and of mastery greatly diminishes. They are component instincts whose function it is to assure that the organism shall follow its own path to death, and to ward off any possible ways of returning to inorganic existence other than those which are immanent in the organism itself. We have no longer to reckon with the organism's puzzling determination (so hard to fit into any context) to maintain its own existence in the face of every obstacle. What we are left with is the fact that the organism wishes to die only in its own fashion. Thus these guardians of life, too, were originally the myrmidons of death. Hence arises the paradoxical situation that the living organism struggles most energetically against events (dangers, in fact) which might help it to attain its life's aim rapidly - by a kind of short-circuit. Such behaviour is, however, precisely what characterizes purely instinctual as contrasted with intelligent efforts.

But let us pause for a moment and reflect. It cannot be so. The sexual instincts, to which the theory of the neuroses gives a quite special place, appear under a very different aspect.

The external pressure which provokes a constantly increasing extent of development has not imposed itself upon *every* organism. Many have succeeded in remaining up to the present time at their lowly level. Many, though not all, such creatures, which must resemble the earliest stages of the higher animals and plants, are, indeed, living to-day. In the same way, the whole path of development to natural death is not trodden by *all* the elementary entities which compose the complicated body of one of the higher organisms. Some of them, the germ-cells, probably retain the original structure of living matter and, after a certain time, with their full complement of inherited and freshly acquired instinctual dispositions, separate themselves from the organism as a whole. These two characteristics may be precisely what enables them to have an independent existence. Under favourable conditions, they begin to develop - that is, to repeat the performance to which they owe their existence; and in the end once again one portion of their substance pursues its development to a finish, while another portion harks back once again as a fresh residual germ to the beginning of the process of development. These germ-cells, therefore, work against the death of the living substance and succeed in winning for it what we can only regard as potential immortality, though that may mean no more than a lengthening of the road to death. We must regard as in the highest degree significant the fact that this function of the germ-cell is reinforced, or only made possible, if it coalesces with another cell similar to itself and yet differing from it.

The instincts which watch over the destinies of these elementary organisms that survive the whole individual, which provide them with a safe shelter while they are defenceless against the stimuli of the external world, which bring about their meeting with other germ-cells, and so on - these constitute the group of the sexual instincts. They are conservative in the same sense as the other instincts in that they bring back earlier states of living substance; but they are conservative to a higher degree in that they are peculiarly resistant to external influences; and they are conservative too in another sense in that they preserve life itself for a comparatively long period.¹ They are the true life instincts. They operate against the purpose of the other instincts, which leads, by reason of their function, to death; and this fact indicates that there is an opposition between them and the other instincts, an opposition whose importance was long ago recognized by the theory of the neuroses. It is as though the life of the organism moved with a vacillating rhythm. One group of instincts rushes forward so as to reach the final aim of life as swiftly as possible; but when a particular stage in the advance has been reached, the other group jerks back to a certain point to make a fresh start and so prolong the journey. And even though it is certain that sexuality and the distinction between the sexes did not exist when life began, the possibility remains that the instincts which were later to be described as sexual may have been in operation from the very first, and it may not be true that it was only at a later time that they started upon their work of opposing the activities of the 'ego-instincts'.²

¹ Yet it is to them alone that we can attribute an internal impulse towards 'progress' and towards higher development! (See below)

² It should be understood from the context that the term 'ego-instincts' is used here as a provisional description and derives from the earliest psycho-analytical terminology.

Let us now hark back for a moment ourselves and consider whether there is any basis at all for these speculations. Is it really the case that, *apart from the sexual instincts*, there are no instincts that do not seek to restore an earlier state of things? that there are none that aim at a state of things which has never yet been attained? I know of no certain example from the organic world that would contradict the characterization I have thus proposed. There is unquestionably no universal instinct towards higher development observable in the animal or plant world, even though it is undeniable that development does in fact occur in that direction. But on the one hand it is often merely a matter of opinion when we declare that one stage of development is higher than another, and on the other hand biology teaches us that higher development in one respect is very frequently balanced or outweighed by involution in another. Moreover there are plenty of animal forms from whose early stages we can infer that their development has, on the contrary, assumed a retrograde character. Both higher development and involution might well be the consequences of adaptation to the pressure of external forces; and in both cases the part played by instincts might be limited to the retention (in the form of an internal source of pleasure) of an obligatory modification.¹

¹ Ferenczi (1913, 137) has reached the same conclusion along different lines: 'If this thought is pursued to its logical conclusion, one must make oneself familiar with the idea of a tendency to perseveration or regression dominating organic life as well, while the tendency to further development, to adaptation, etc., would become active only as a result of external stimuli.'

It may be difficult, too, for many of us, to abandon the belief that there is an instinct towards perfection at work in human beings, which has brought them to their present high level of intellectual achievement and ethical sublimation and which may be expected to watch over their development into supermen. I have no faith, however, in the existence of any such internal instinct and I cannot see how this benevolent illusion is to be preserved. The present development of human beings requires, as it seems to me, no different explanation from that of animals. What appears in a minority of human individuals as an untiring impulsion towards further perfection can easily be understood as a result of the instinctual repression upon which is based all that is most precious in human civilization. The repressed instinct never ceases to strive for complete satisfaction, which would consist in the repetition of a primary experience of satisfaction. No substitutive or reactive formations and no sublimations will suffice to remove the repressed instinct's persisting tension; and it is the difference in amount between the pleasure of satisfaction which is *demanded* and that which is actually *achieved* that provides the driving factor which will permit of no halting at any position attained, but, in the poet's words, '*ungebändigt immer vorwärts dringt*'.¹ The backward path that leads to complete satisfaction is as a rule obstructed by the resistances which maintain the repressions. So there is no alternative but to advance in the direction in which growth is still free - though with no prospect of bringing the process to a conclusion or of being able to reach the goal. The processes involved in the formation of a neurotic phobia, which is nothing else than an attempt at flight from the satisfaction of an instinct, present us with a model of the manner of origin of this supposititious 'instinct towards perfection' - an instinct which cannot possibly be attributed to *every* human being. The *dynamic* conditions for its development are, indeed, universally present; but it is only in rare cases that the *economic* situation appears to favour the production of the phenomenon.

I will add only a word to suggest that the efforts of Eros to combine organic substances into ever larger unities probably provide a substitute for this 'instinct towards perfection' whose existence we cannot admit. The phenomena that are attributed to it seem capable of explanation by these efforts of Eros taken in conjunction with the results of repression.

¹ Mephistopheles in *Faust*, Part I.

VI

The upshot of our enquiry so far has been the drawing of a sharp distinction between the 'ego-instincts' and the sexual instincts, and the view that the former exercise pressure towards death and the latter towards a prolongation of life. But this conclusion is bound to be unsatisfactory in many respects even to ourselves. Moreover, it is actually only of the former group of instincts that we can predicate a conservative, or rather retrograde, character corresponding to a compulsion to repeat. For on our hypothesis the ego-instincts arise from the coming to life of inanimate matter and seek to restore the inanimate state; whereas as regards the sexual instincts, though it is true that they reproduce primitive states of the organism, what they are clearly aiming at by every possible means is the coalescence of two germ-cells which are differentiated in a particular way. If this union is not effected, the germ-cell dies along with all the other elements of the multicellular organism. It is only on this condition that the sexual function can prolong the cell's life and lend it the appearance of immortality. But what is the important event in the development of living substance which is being repeated in sexual reproduction, or in its fore-runner, the conjugation of two protista? We cannot say; and we should consequently feel relieved if the whole structure of our argument turned out to be mistaken. The opposition between the ego or death instincts and the sexual or life instincts would then cease to hold and the compulsion to repeat would no longer possess the importance we have ascribed to it.

Let us turn back, then, to one of the assumptions that we have already made, with the expectation that we shall be able to give it a categorical denial. We have drawn far-reaching conclusions from the hypothesis that all living substance is bound to die from internal causes. We made this assumption thus carelessly because it does not seem to us to *be* an assumption. We are accustomed to think that such is the fact, and we are strengthened in our thought by the writings of our poets. Perhaps we have adopted the belief because there is some comfort in it. If we are to die ourselves, and first to lose in death those who are dearest to us, it is easier to submit to a remorseless law of nature, to the sublime *Ἀναρχή*, than to a chance which might perhaps have been escaped. It may be, however, that this belief in the internal necessity of dying is only another of those illusions which we have created *'um die Schwere des Daseins zu ertragen'*. It is certainly not a *primaeval* belief. The notion of 'natural death' is quite foreign to primitive races; they attribute every death that occurs among them to the influence of an enemy or of an evil spirit. We must therefore turn to biology in order to test the validity of the belief.

If we do so, we may be astonished to find how little agreement there is among biologists on the subject of natural death and in fact that the whole concept of death melts away under their hands. The fact that there is a fixed average duration of life at least among the higher animals naturally argues in favour of there being such a thing as death from natural causes. But this impression is countered when we consider that certain large animals and certain gigantic arboreal growths reach a very advanced age and one which cannot at present be computed. According to the large conception of Wilhelm Fliess, all the phenomena of life exhibited by organisms - and also, no doubt, their death - are linked with the completion of fixed periods, which express the dependence of two kinds of living substance (one male and the other female) upon the solar year. When we see, however, how easily and how extensively the influence of external forces is able to modify the date of the appearance of vital phenomena (especially in the plant world) - to precipitate them or hold them back - doubts must be cast upon the rigidity of Fliess's formulas or at least upon whether the laws laid down by him are the sole determining factors.

The greatest interest attaches from our point of view to the treatment given to the subject of the duration of life and the death of organisms in the writings of Weismann (1882, 1884, 1892, etc.) It was he who introduced the division of living substance into mortal and immortal parts. The mortal part is the body in the narrower sense - the 'soma' - which alone is subject to natural death. The germ-cells, on the other hand, are potentially immortal, in so far as they are able, under certain favourable conditions, to develop into a new individual, or, in other words, to surround themselves with a new soma. (Weismann, 1884.)

What strikes us in this is the unexpected analogy with our own view, which was arrived at along such a different path. Weismann, regarding living substance morphologically, sees in it one portion which is destined to die - the soma, the body apart from the substance concerned with sex and inheritance - and an immortal portion - the germ-plasm, which is concerned with the survival of the species, with reproduction. We, on the other hand, dealing not with the living substance but with the forces operating in it, have been led to distinguish two kinds of instincts: those which seek to lead what is living to death, and others, the sexual instincts, which are perpetually attempting and achieving a renewal of life. This sounds like a dynamic corollary to Weismann's morphological theory.

But the appearance of a significant correspondence is dissipated as soon as we discover Weismann's views on the problem of death. For he only relates the distinction between the mortal soma and the immortal germ-plasm to *multicellular* organisms; in unicellular organisms the individual and the reproductive cell are still one and the same (Weismann, 1882, 38). Thus he considers that unicellular organisms are potentially immortal, and that death only makes its appearance with the multicellular metazoa. It is true that this death of the higher organisms is a natural one, a death from internal causes; but it is not founded on any primal characteristic of living substance (Weismann, 1884, 84) and cannot be regarded as an absolute necessity with its basis in the very nature of life (Weismann, 1882, 33). Death is rather a matter of expediency, a manifestation of adaptation to the external conditions of life; for, when once the cells of the body have been divided into soma and germ-plasm, an unlimited duration of individual life would become a quite pointless luxury. When this differentiation had been made in the multicellular organisms, death became possible and expedient. Since then, the soma of the higher organisms has died at fixed periods for internal reasons, while the protista have remained immortal. It is not the case, on the other hand, that reproduction was only introduced at the same time as death. On the contrary, it is a primal characteristic of living matter, like growth (from which it originated), and life has been continuous from its first beginning upon earth. (Weismann, 1884, 84 f.)

It will be seen at once that to concede in this way that higher organisms have a natural death is of very little help to us. For if death is a *late* acquisition of organisms, then there can be no question of there having been death instincts from the very beginning of life on this earth. Multicellular organisms may die for internal reasons, owing to defective differentiation or to imperfections in their metabolism, but the matter is of no interest from the point of view of our problem. An account of the origin of death such as this is moreover far less at variance with our habitual modes of thought than the strange assumption of 'death instincts'.

The discussion which followed upon Weismann's suggestions led, so far as I can see, to no conclusive results in any direction.¹ Some writers returned to the views of Goette (1883), who regarded death as a direct result of reproduction. Hartmann (1906, 29) does not regard the appearance of a 'dead body' - a dead portion of the living substance - as the criterion of death, but defines death as 'the termination of individual development'. In this sense protozoa too are mortal; in their case death always coincides with reproduction, but is to some extent obscured by it, since the whole substance of the parent animal may be transmitted directly into the young offspring.

Soon afterwards research was directed to the experimental testing on unicellular organisms of the alleged immortality of living substance. An American biologist, Woodruff, experimenting with a ciliate infusorian, the 'slipper-animalcule', which reproduces by fission into two individuals, persisted until the 3029th generation (at which point he broke off the experiment), isolating one of the part-products on each occasion and placing it in fresh water. This remote descendent of the first slipper-animalcule was just as lively as its ancestor and showed no signs of ageing or degeneration. Thus, in so far as figures of this kind prove anything, the immortality of the protista seemed to be experimentally demonstrable.²

¹ Cf. Hartmann (1906), Lipschütz (1914) and Doflein (1919).

² For this and what follows see Lipschütz (1914, 26 and 52 ff.).

Other experimenters arrived at different results. Maupas, Calkins and others, in contrast to Woodruff, found that after a certain number of divisions these infusoria become weaker, diminish in size, suffer the loss of some part of their organization and eventually die, unless certain recuperative measures are applied to them. If this is so, protozoa would appear to die after a phase of senescence exactly like the higher animals - thus completely contradicting Weismann's assertion that death is a late acquisition of living organisms.

From the aggregate of these experiments two facts emerge which seem to offer us a firm footing.

First: If two of the animalculae, at the moment before they show signs of senescence, are able to coalesce with each other, that is to 'conjugate' (soon after which they once more separate), they are saved from growing old and become 'rejuvenated'. Conjugation is no doubt the fore-runner of the sexual reproduction of higher creatures; it is as yet unconnected with propagation and is limited to the mixing of the substances of the two individuals. (Weismann's 'amphimixis'.) The recuperative effects of conjugation can, however, be replaced by certain stimulating agents, by alterations in the composition of the fluid which provides their nourishment, by raising their temperature or by shaking them. We are reminded of the celebrated experiment made by J. Loeb, in which, by means of certain chemical stimuli, he induced segmentation in sea-urchins' eggs - a process which can normally occur only after fertilization.

Secondly: It is probable nevertheless that infusoria die a natural death as a result of their own vital processes. For the contradiction between Woodruff's findings and the others is due to his having provided each generation with fresh nutrient fluid. If he omitted to do so, he observed the same signs of senescence as the other experimenters. He concluded that the animalculae were injured by the products of metabolism which they extruded into the surrounding fluid. He was then able to prove conclusively that it was only the products of its *own* metabolism which had fatal results for the particular kind of animalcule. For the same animalculae which inevitably perished if they were crowded together in their own nutrient fluid flourished in a solution which was over-saturated with the waste products of a distantly related species. An infusorian, therefore, if it is left to itself, dies a natural death owing to its incomplete avoidance of the products of its own metabolism. (It may be that the same incapacity is the ultimate cause of the death of all higher animals as well.)

At this point the question may well arise in our minds whether any object whatever is served by trying to solve the problem of natural death from a study of the protozoa. The primitive organization of these creatures may conceal from our eyes important conditions which, though in fact present in them too, only become *visible* in higher animals where they are able to find morphological expression. And if we abandon the morphological point of view and adopt the dynamic one, it becomes a matter of complete indifference to us whether natural death can be shown to occur in protozoa or not. The substance which is later recognized as being immortal has not yet become separated in them from the mortal one. The instinctual forces which seek to conduct life into death may also be operating in protozoa from the first, and yet their effects may be so completely concealed by the life-preserving forces that it may be very hard to find any direct evidence of their presence. We have seen, moreover, that the observations made by biologists allow us to assume that internal processes of this kind leading to death do occur also in protista. But even if protista turned out to be immortal in Weismann's sense, his assertion that death is a late acquisition would apply only to its *manifest* phenomena and would not make impossible the assumption of processes *tending* towards it.

Thus our expectation that biology would flatly contradict the recognition of death instincts has not been fulfilled. We are at liberty to continue concerning ourselves with their possibility, if we have other reasons for doing so. The striking similarity between Weismann's distinction of soma and germ-plasm and our separation of the death instincts from the life instincts persists and retains its significance.

We may pause for a moment over this pre-eminently dualistic view of instinctual life. According to E. Hering's theory, two kinds of processes are constantly at work in living substance, operating in contrary directions, one constructive or assimilatory and the other destructive or dissimilatory. May we venture to recognize in these two directions taken by the vital processes the activity of our two instinctual impulses, the life instincts and the death instincts? There is something else, at any rate, that we cannot remain blind to. We have unwittingly steered our course into the harbour of Schopenhauer's philosophy. For him death is the 'true result and to that extent the purpose of life',¹ while the sexual instinct is the embodiment of the will to live.

¹ Schopenhauer (1851; *Sämtliche Werke*, ed. Hübscher, 1938, 5, 236).

Let us make a bold attempt at another step forward. It is generally considered that the union of a number of cells into a vital association - the multicellular character of organisms - has become a means of prolonging their life. One cell helps to preserve the life of another, and the community of cells can survive even if individual cells have to die. We have already heard that conjugation, too, the temporary coalescence of two unicellular organisms, has a life-preserving and rejuvenating effect on both of them. Accordingly, we might attempt to apply the libido theory which has been arrived at in psycho-analysis to the mutual relationship of cells. We might suppose that the life instincts or sexual instincts which are active in each cell take the other cells as their object, that they partly neutralize the death instincts (that is, the processes set up by them) in those cells and thus preserve their life; while the other cells do the same for *them*, and still others sacrifice themselves in the performance of this libidinal function. The germ-cells themselves would behave in a completely 'narcissistic' fashion - to use the phrase that we are accustomed to use in the theory of the neuroses to describe a whole individual who retains his libido in his ego and pays none of it out in object-cathexes. The germ-cells require their libido, the activity of their life instincts, for themselves, as a reserve against their later momentous constructive activity. (The cells of the malignant neoplasms which destroy the organism should also perhaps be described as narcissistic in this same sense: pathology is prepared to regard their germs as innate and to ascribe embryonic attributes to them.) In this way the libido of our sexual instincts would coincide with the Eros of the poets and philosophers which holds all living things together.

Here then is an opportunity for looking back over the slow development of our libido theory. In the first instance the analysis of the transference neuroses forced upon our notice the opposition between the 'sexual instincts', which are directed towards an object, and certain other instincts, with which we were very insufficiently acquainted and which we described provisionally as the 'ego-instincts'. A foremost place among these was necessarily given to the instincts serving the self-preservation of the individual. It was impossible to say what other distinctions were to be drawn among them. No knowledge would have been more valuable as a foundation for true psychological science than an approximate grasp of the common characteristics and possible distinctive features of the instincts. But in no region of psychology were we groping more in the dark. Everyone assumed the existence of as many instincts or 'basic instincts' as he chose, and juggled with them like the ancient Greek natural philosophers with their four elements - earth, air, fire and water. Psycho-analysis, which could not escape making *some* assumption about the instincts, kept at first to the popular division of instincts typified in the phrase 'hunger and love'. At least there was nothing arbitrary in this; and by its help the analysis of the psychoneuroses was carried forward quite a distance. The concept of 'sexuality', and at the same time of the sexual instinct, had, it is true, to be extended so as to cover many things which could not be classed under the reproductive function; and this caused no little hubbub in an austere, respectable or merely hypocritical world.

The next step was taken when psycho-analysis felt its way closer towards the psychological ego, which it had first come to know only as a repressive, censoring agency, capable of erecting protective structures and reactive formations. Critical and far-seeing minds had, it is true, long since objected to the concept of libido being restricted to the energy of the sexual instincts directed towards an object. But they failed to explain how they had arrived at their better knowledge or to derive from it anything of which analysis could make use. Advancing more cautiously, psycho-analysis observed the regularity with which libido is withdrawn from the object and directed on to the ego (the process of introversion); and, by studying the libidinal development of children in its earliest phases, came to the conclusion that the ego is the true and original reservoir of libido, and that it is only from that reservoir that libido is extended on to objects. The ego now found its position among sexual objects and was at once given the foremost place among them. Libido which was in this way lodged in the ego was described as 'narcissistic'.¹ This narcissistic libido was of course also a manifestation of the force of the sexual instinct in the analytical sense of those words, and it had necessarily to be identified with the 'self-preservative instincts' whose existence had been recognized from the first. Thus the original opposition between the ego-instincts and the sexual instincts proved to be inadequate. A portion of the ego-instincts was seen to be libidinal; sexual instincts - probably alongside others - operated in the ego. Nevertheless we are justified in saying that the old formula which lays it down that psychoneuroses are based on a conflict between ego-instincts and sexual instincts contains nothing that we need reject to-day. It is merely that the distinction between the two kinds of instinct, which was originally regarded as in some sort of way *qualitative*, must now be characterized differently - namely as being *topographical*. And in particular it is still true that the transference neuroses, the essential subject of psycho-analytic study, are the result of a conflict between the ego and the libidinal cathexis of objects.

But it is all the more necessary for us to lay stress upon the libidinal character of the self-preservative instincts now that we are venturing upon the further step of recognizing the sexual instinct as Eros, the preserver of all things, and of deriving the narcissistic libido of the ego from the stores of libido by means of which the cells of the soma are attached to one another. But we now find ourselves suddenly faced by another question. If the self-preservative instincts too are of a libidinal nature, are there perhaps no other instincts whatever but the libidinal ones? At all events there are none other visible. But in that case we shall after all be driven to agree with the critics who suspected from the first that psycho-analysis explains *everything* by sexuality, or with innovators like Jung who, making a hasty judgement, have used the word 'libido' to mean instinctual force in general. Must not this be so?

¹ See my paper on narcissism (1914c).

It was not our *intention* at all events to produce such a result. Our argument had as its point of departure a sharp distinction between ego-instincts, which we equated with death instincts, and sexual instincts, which we equated with life instincts. (We were prepared at one stage to include the so-called self-preservative instincts of the ego among the death instincts; but we subsequently corrected ourselves on this point and withdrew it.) Our views have from the very first been *dualistic*, and to-day they are even more definitely dualistic than before - now that we describe the opposition as being, not between ego-instincts and sexual instincts but between life instincts and death instincts. Jung's libido theory is on the contrary *monistic*; the fact that he has called his one instinctual force 'libido' is bound to cause confusion, but need not affect us otherwise. We suspect that instincts other than those of self-preservation operate in the ego, and it ought to be possible for us to point to them. Unfortunately, however, the analysis of the ego has made so little headway that it is very difficult for us to do so. It is possible, indeed, that the libidinal instincts in the ego may be linked in a peculiar manner with these other ego-instincts which are still strange to us. Even before we had any clear understanding of narcissism, psycho-analysts had a suspicion that the 'ego-instincts' had libidinal components attached to them. But these are very uncertain possibilities, to which our opponents will pay very little attention. The difficulty remains that psycho-analysis has not enabled us hitherto to point to any instincts other than the libidinal ones. That, however, is no reason for our falling in with the conclusion that no others in fact exist.

In the obscurity that reigns at present in the theory of the instincts, it would be unwise to reject any idea that promises to throw light on it. We started out from the great opposition between the life and death instincts. Now object-love itself presents us with a second example of a similar polarity - that between love (or other affection) and hate (or aggressiveness). If only we could succeed in relating these two polarities to each other and in deriving one from the other! From the very first we recognized the presence of a sadistic component in the sexual instinct.¹ As we know, it can make itself independent and can, in the form of a perversion, dominate an individual's entire sexual activity. It also emerges as a predominant component instinct in one of the 'pregenital organizations', as I have named them. But how can the sadistic instinct, whose aim it is to injure the object, be derived from Eros, the preserver of life? Is it not plausible to suppose that this sadism is in fact a death instinct which, under the influence of the narcissistic libido, has been forced away from the ego and has consequently only emerged in relation to the object? It now enters the service of the sexual function. During the oral stage of organization of the libido, the act of obtaining erotic mastery over an object coincides with that object's destruction; later, the sadistic instinct separates off, and finally, at the stage of genital primacy, it takes on, for the purposes of reproduction, the function of overpowering the sexual object to the extent necessary for carrying out the sexual act. It might indeed be said that the sadism which has been forced out of the ego has pointed the way for the libidinal components of the sexual instinct, and that these follow after it to the object. Wherever the original sadism has undergone no mitigation or intermixture, we find the familiar ambivalence of love and hate in erotic life.

If such an assumption as this is permissible, then we have met the demand that we should produce an example of a death instinct - though, it is true, a displaced one. But this way of looking at things is very far from being easy to grasp and creates a positively mystical impression. It looks suspiciously as though we were trying to find a way out of a highly embarrassing situation at any price. We may recall, however, that there is nothing new in an assumption of this kind. We put one forward on an earlier occasion, before there was any question of an embarrassing situation. Clinical observations led us at that time to the view that masochism, the component instinct which is complementary to sadism, must be regarded as sadism that has been turned round upon the subject's own ego.² But there is no difference in principle between an instinct turning from an object to the ego and its turning from the ego to an object - which is the new point now under discussion. Masochism, the turning round of the instinct upon the subject's own ego, would in that case be a return to an earlier phase of the instinct's history, a regression. The account that was formerly given of masochism requires emendation as being too sweeping in one respect: there *might* be such a thing as primary masochism - a possibility which I had contested at that time.³

¹ This was already so in the first edition of *Three Essays on the Theory of Sexuality* in 1905.

² See my *Three Essays* (1905d) and 'Instincts and their Vicissitudes' (1915c).

³ A considerable portion of these speculations have been anticipated by Sabina Spielrein (1912) in an instructive and interesting paper which, however, is unfortunately not entirely clear to me. She there describes the sadistic components of the sexual instinct as 'destructive'. A. Stürke (1914), again, has attempted to identify the concept of libido itself with the biological concept (assumed on theoretical grounds) of an impetus towards death. See also Rank (1907). All these discussions, like that in the text, give evidence of the demand for a clarification of the theory of the instincts such as has not yet been achieved.

Let us, however, return to the self-preservative sexual instincts. The experiments upon protista have already shown us that conjugation - that is, the coalescence of two individuals which separate soon afterwards without any subsequent cell-division occurring - has a strengthening and rejuvenating effect upon both of them.¹ In later generations they show no signs of degenerating and seem able to put up a longer resistance to the injurious effects of their own metabolism. This single observation may, I think, be taken as typical of the effect produced by sexual union as well. But how is it that the coalescence of two only slightly different cells can bring about this renewal of life? The experiment which replaces the conjugation of protozoa by the application of chemical or even of mechanical stimuli (cf. Lipschütz, 1914) enables us to give what is no doubt a conclusive reply to this question. The result is brought about by the influx of fresh amounts of stimulus. This tallies well with the hypothesis that the life process of the individual leads for internal reasons to an abolition of chemical tensions, that is to say, to death, whereas union with the living substance of a different individual increases those tensions, introducing what may be described as fresh 'vital differences' which must then be lived off. As regards this dissimilarity there must of course be one or more optima. The dominating tendency of mental life, and perhaps of nervous life in general, is the effort to reduce, to keep constant or to remove internal tension due to stimuli (the 'Nirvana principle', to borrow a term from Barbara Low) - a tendency which finds expression in the pleasure principle; and our recognition of that fact is one of our strongest reasons for believing in the existence of death instincts.

¹ See the account quoted above p. 3748 from Lipschütz (1914).

But we still feel our line of thought appreciably hampered by the fact that we cannot ascribe to the sexual instinct the characteristic of a compulsion to repeat which first put us on the track of the death instincts. The sphere of embryonic developmental processes is no doubt extremely rich in such phenomena of repetition; the two germ-cells that are involved in sexual reproduction and their life history are themselves only repetitions of the beginnings of organic life. But the essence of the processes to which sexual life is directed is the coalescence of two cell-bodies. That alone is what guarantees the immortality of the living substance in the higher organisms.

In other words, we need more information on the origin of sexual reproduction and of the sexual instincts in general. This is a problem which is calculated to daunt an outsider and which the specialists themselves have not yet been able to solve. We shall therefore give only the briefest summary of whatever seems relevant to our line of thought from among the many discordant assertions and opinions.

One of these views deprives the problem of reproduction of its mysterious fascination by representing it as a part manifestation of growth. (Cf. multiplication by fission, sprouting or gemmation.) The origin of reproduction by sexually differentiated germ-cells might be pictured along sober Darwinian lines by supposing that the advantage of amphimixis, arrived at on some occasion by the chance conjugation of two protista, was retained and further exploited in later development.¹ On this view 'sex' would not be anything very ancient; and the extra ordinarily violent instincts whose aim it is to bring about sexual union would be repeating something that had once occurred by chance and had since become established as being advantageous.

The question arises here, as in the case of death, whether we do right in ascribing to protista those characteristics alone which they actually exhibit, and whether it is correct to assume that forces and processes which become visible only in the higher organisms originated in those organisms for the first time. The view of sexuality we have just mentioned is of little help for our purposes. The objection may be raised against it that it postulates the existence of life instincts already operating in the simplest organisms; for otherwise conjugation, which works counter to the course of life and makes the task of ceasing to live more difficult, would not be retained and elaborated but would be avoided. If, therefore, we are not to abandon the hypothesis of death instincts, we must suppose them to be associated from the very first with life instincts. But it must be admitted that in that case we shall be working upon an equation with two unknown quantities.

¹ Though Weismann (1892) denies this advantage as well: 'In no case does fertilization correspond to a rejuvenescence or renewal of life, nor is its occurrence necessary in order that life may endure: it is merely an arrangement which renders possible the intermingling of two different hereditary tendencies.' He nevertheless believes that an intermingling of this kind leads to an increase in the variability of the organism concerned.

Apart from this, science has so little to tell us about the origin of sexuality that we can liken the problem to a darkness into which not so much as a ray of a hypothesis has penetrated. In quite a different region, it is true, we *do* meet with such a hypothesis; but it is of so fantastic a kind - a myth rather than a scientific explanation - that I should not venture to produce it here, were it not that it fulfils precisely the one condition whose fulfilment we desire. For it traces the origin of an instinct to *a need to restore an earlier state of things*.

What I have in mind is, of course, the theory which Plato put into the mouth of Aristophanes in the *Symposium*, and which deals not only with the *origin* of the sexual instinct but also with the most important of its variations in relation to its object. 'The original human nature was not like the present, but different. In the first place, the sexes were originally three in number, not two as they are now; there was man, woman, and the union of the two. . . .' Everything about these primaevial men was double: they had four hands and four feet, two faces, two privy parts, and so on. Eventually Zeus decided to cut these men in two, 'like a sorb-apple which is halved for pickling'. After the division had been made, 'the two parts of man, each desiring his other half, came together, and threw their arms about one another eager to grow into one'.¹

¹ I have to thank Professor Heinrich Gomperz, of Vienna, for the following discussion on the origin of the Platonic myth, which I give partly in his own words. It is to be remarked that what is essentially the same theory is already to be found in the Upanishads. For we find the following passage in the *Bṛihadâraṇyaka-upanishad*, 1, 4, 3, where the origin of the world from the Atman (the Self or Ego) is described: 'But he felt no delight. Therefore a man who is lonely feels no delight. He wished for a second. He was so large as man and wife together. He then made this his Self to fall in two, and then arose husband and wife. Therefore Yagnavalkya said: "We two are thus (each of us) like half a shell." Therefore the void which was there, is filled by the wife.'

The *Bṛihadâraṇyaka-upanishad* is the most ancient of all the Upanishads and no competent authority dates it later than about the year 800 B.C. In contradiction to the prevailing opinion, I should hesitate to give an unqualified denial to the possibility of Plato's myth being derived, even if it were only indirectly, from the Indian source, since a similar possibility cannot be excluded in the case of the doctrine of transmigration. But even if a derivation of this kind (through the Pythagoreans in the first instance) were established, the significance of the coincidence between the two trains of thought would scarcely be diminished. For Plato would not have adopted a story of this kind which had somehow reached him through some oriental tradition - to say nothing of giving it so important a place - unless it had struck him as containing an element of truth.

In a paper devoted to a systematic examination of this line of thought before the time of Plato, Ziegler (1913) traces it back to Babylonian origins.

Shall we follow the hint given us by the poet-philosopher, and venture upon the hypothesis that living substance at the time of its coming to life was torn apart into small particles, which have ever since endeavoured to reunite through the sexual instincts? that these instincts, in which the chemical affinity of inanimate matter persisted, gradually succeeded, as they developed through the kingdom of the protista, in overcoming the difficulties put in the way of that endeavour by an environment charged with dangerous stimuli - stimuli which compelled them to form a protective cortical layer? that these splintered fragments of living substance in this way attained a multicellular condition and finally transferred the instinct for reuniting, in the most highly concentrated form, to the germ-cells? - But here, I think, the moment has come for breaking off.

Not, however, without the addition of a few words of critical reflection. It may be asked whether and how far I am myself convinced of the truth of the hypotheses that have been set out in these pages. My answer would be that I am not convinced myself and that I do not seek to persuade other people to believe in them. Or, more precisely, that I do not know how far I believe in them. There is no reason, as it seems to me, why the emotional factor of conviction should enter into this question at all. It is surely possible to throw oneself into a line of thought and to follow it wherever it leads out of simple scientific curiosity, or, if the reader prefers, as an *advocatus diaboli*, who is not on that account himself sold to the devil. I do not dispute the fact that the third step in the theory of the instincts, which I have taken here, cannot lay claim to the same degree of certainty as the two earlier ones - the extension of the concept of sexuality and the hypothesis of narcissism. These two innovations were a direct translation of observation into theory and were no more open to sources of error than is inevitable in all such cases. It is true that my assertion of the regressive character of instincts also rests upon observed material - namely on the facts of the compulsion to repeat. It may be, however, that I have overestimated their significance. And in any case it is impossible to pursue an idea of this kind except by repeatedly combining factual material with what is purely speculative and thus diverging widely from empirical observation. The more frequently this is done in the course of constructing a theory, the more untrustworthy, as we know, must be the final result. But the degree of uncertainty is not assignable. One may have made a lucky hit or one may have gone shamefully astray. I do not think a large part is played by what is called 'intuition' in work of this kind. From what I have seen of intuition, it seems to me to be the product of a kind of intellectual impartiality. Unfortunately, however, people are seldom impartial where ultimate things, the great problems of science and life, are concerned. Each of us is governed in such cases by deep-rooted internal prejudices, into whose hands our speculation unwittingly plays. Since we have such good grounds for being distrustful, our attitude towards the results of our own deliberations cannot well be other than one of cool benevolence. I hasten to add, however, that self-criticism such as this is far from binding one to any special tolerance towards dissentient opinions. It is perfectly legitimate to reject remorselessly theories which are contradicted by the very first steps in the analysis of observed facts, while yet being aware at the same time that the validity of one's own theory is only a provisional one.

We need not feel greatly disturbed in judging our speculation upon the life and death instincts by the fact that so many bewildering and obscure processes occur in it - such as one instinct being driven out by another or an instinct turning from the ego to an object, and so on. This is merely due to our being obliged to operate with the scientific terms, that is to say with the figurative language, peculiar to psychology (or, more precisely, to depth psychology). We could not otherwise describe the processes in question at all, and indeed we could not have become aware of them. The deficiencies in our description would probably vanish if we were already in a position to replace the psychological terms by physiological or chemical ones. It is true that they too are only part of a figurative language; but it is one with which we have long been familiar and which is perhaps a simpler one as well.

On the other hand it should be made quite clear that the uncertainty of our speculation has been greatly increased by the necessity for borrowing from the science of biology. Biology is truly a land of unlimited possibilities. We may expect it to give us the most surprising information and we cannot guess what answers it will return in a few dozen years to the questions we have put to it. They may be of a kind which will blow away the whole of our artificial structure of hypotheses. If so, it may be asked why I have embarked upon such a line of thought as the present one, and in particular why I have decided to make it public. Well - I cannot deny that some of the analogies, correlations and connections which it contains seemed to me to deserve consideration.¹

¹ I will add a few words to clarify our terminology, which has undergone some development in the course of the present work. We came to know what the 'sexual instincts' were from their relation to the sexes and to the reproductive function. We retained this name after we had been obliged by the findings of psycho-analysis to connect them less closely with reproduction. With the hypothesis of narcissistic libido and the extension of the concept of libido to the individual cells, the sexual instinct was transformed for us into Eros, which seeks to force together and hold together the portions of living substance. What are commonly called the sexual instincts are looked upon by us as the part of Eros which is directed towards objects. Our speculations have suggested that Eros operates from the beginning of life and appears as a 'life instinct' in opposition to the 'death instinct' which was brought into being by the coming to life of inorganic substance. These speculations seek to solve the riddle of life by supposing that these two instincts were struggling with each other from the very first. It is not so easy, perhaps, to follow the transformations through which the concept of the 'ego-instincts' has passed. To begin with we applied that name to all the instinctual trends (of which we had no closer knowledge) which could be distinguished from the sexual instincts directed towards an object; and we opposed the ego-instincts to the sexual instincts of which the libido is the manifestation. Subsequently we came to closer grips with the analysis of the ego and recognized that a portion of the 'ego-instincts' is also of a libidinal character and has taken the subject's own ego as its object. These narcissistic self-preservative instincts had thenceforward to be counted among the libidinal sexual instincts. The opposition between the ego-instincts and the sexual instincts was transformed into one between the ego-instincts and the object-instincts, both of a libidinal nature. But in its place a fresh opposition appeared between the libidinal (ego- and object-) instincts and others, which must be presumed to be present in the ego and which may perhaps actually be observed in the destructive instincts. Our speculations have transformed this opposition into one between the life instincts (Eros) and the death instincts.

VII

If it is really the case that seeking to restore an earlier state of things is such a universal characteristic of instincts, we need not be surprised that so many processes take place in mental life independently of the pleasure principle. This characteristic would be shared by all the component instincts and in their case would aim at returning once more to a particular stage in the course of development. These are matters over which the pleasure principle has as yet no control; but it does not follow that any of them are necessarily opposed to it, and we have still to solve the problem of the relation of the instinctual processes of repetition to the dominance of the pleasure principle.

We have found that one of the earliest and most important functions of the mental apparatus is to bind the instinctual impulses which impinge on it, to replace the primary process prevailing in them by the secondary process and convert their freely mobile cathectic energy into a mainly quiescent (tonic) cathexis. While this transformation is taking place no attention can be paid to the development of unpleasure; but this does not imply the suspension of the pleasure principle. On the contrary, the transformation occurs on *behalf* of the pleasure principle; the binding is a preparatory act which introduces and assures the dominance of the pleasure principle.

Let us make a sharper distinction than we have hitherto made between function and tendency. The pleasure principle, then, is a tendency operating in the service of a function whose business it is to free the mental apparatus entirely from excitation or to keep the amount of excitation in it constant or to keep it as low as possible. We cannot yet decide with certainty in favour of any of these ways of putting it; but it is clear that the function thus described would be concerned with the most universal endeavour of all living substance - namely to return to the quiescence of the inorganic world. We have all experienced how the greatest pleasure attainable by us, that of the sexual act, is associated with a momentary extinction of a highly intensified excitation. The binding of an instinctual impulse would be a preliminary function designed to prepare the excitation for its final elimination in the pleasure of discharge.

This raises the question of whether feelings of pleasure and unpleasure can be produced equally from bound and from unbound excitatory processes. And there seems to be no doubt whatever that the unbound or primary processes give rise to far more intense feelings in both directions than the bound or secondary ones. Moreover the primary processes are the earlier in time; at the beginning of mental life there are no others, and we may infer that if the pleasure principle had not already been operative in *them* it could never have been established for the later ones. We thus reach what is at bottom no very simple conclusion, namely that at the beginning of mental life the struggle for pleasure was far more intense than later but not so unrestricted: it had to submit to frequent interruptions. In later times the dominance of the pleasure principle is very much more secure, but it itself has no more escaped the process of taming than the other instincts in general. In any case, whatever it is that causes the appearance of feelings of pleasure and unpleasure in processes of excitation must be present in the secondary process just as it is in the primary one.

Here might be the starting-point for fresh investigations. Our consciousness communicates to us feelings from within not only of pleasure and unpleasure but also of a peculiar tension which in its turn can be either pleasurable or unpleasurable. Should the difference between these feelings enable us to distinguish between bound and unbound processes of energy? or is the feeling of tension to be related to the absolute magnitude, or perhaps to the level, of the cathexis, while the pleasure and unpleasure series indicates a change in magnitude of the cathexis *within a given unit of time*? Another striking fact is that the life instincts have so much more contact with our internal perception - emerging as breakers of the peace and constantly producing tensions whose release is felt as pleasure - while the death instincts seem to do their work unobtrusively. The pleasure principle seems actually to serve the death instincts. It is true that it keeps watch upon stimuli from without, which are regarded as dangers by both kinds of instincts; but it is more especially on guard against increases of stimulation from within, which would make the task of living more difficult. This in turn raises a host of other questions to which we can at present find no answer. We must be patient and await fresh methods and occasions of research. We must be ready, too, to abandon a path that we have followed for a time, if it seems to be leading to no good end. Only believers, who demand that science shall be a substitute for the catechism they have given up, will blame an investigator for developing or even transforming his views. We may take comfort, too, for the slow advances of our scientific knowledge in the words of the poet:

Was man nicht erfliegen kann, muss man erhinken.

Die Schrift sagt, es ist keine Sünde zu hinken.

GROUP PSYCHOLOGY AND THE ANALYSIS OF THE EGO

I

INTRODUCTION

The contrast between individual psychology and social or group psychology, which at a first glance may seem to be full of significance, loses a great deal of its sharpness when it is examined more closely. It is true that individual psychology is concerned with the individual man and explores the paths by which he seeks to find satisfaction for his instinctual impulses; but only rarely and under certain exceptional conditions is individual psychology in a position to disregard the relations of this individual to others. In the individual's mental life someone else is invariably involved, as a model, as an object, as a helper, as an opponent; and so from the very first individual psychology, in its extended but entirely justifiable sense of the words, is at the same time social psychology as well.

The relations of an individual to his parents and to his brothers and sisters, to the object of his love, and to his physician - in fact all the relations which have hitherto been the chief subject of psycho-analytic research - may claim to be considered as social phenomena; and in this respect they may be contrasted with certain other processes, described by us as 'narcissistic', in which the satisfaction of the instincts is partially or totally withdrawn from the influence of other people. The contrast between social and narcissistic - Bleuler would perhaps call them 'autistic' - mental acts therefore falls wholly within the domain of individual psychology, and is not well calculated to differentiate it from a social or group psychology.

The individual in the relations which have already been mentioned - to his parents and to his brothers and sisters, to the person he is in love with, to his friend, and to his physician - comes under the influence of only a single person, or of a very small number of persons, each one of whom has become enormously important to him. Now in speaking of social or group psychology it has become usual to leave these relations on one side and to isolate as the subject of inquiry the influencing of an individual by a large number of people simultaneously, people with whom he is connected by something, though otherwise they may in many respects be strangers to him. Group psychology is therefore concerned with the individual man as a member of a race, of a nation, of a caste, of a profession, of an institution, or as a component part of a crowd of people who have been organized into a group at some particular time for some definite purpose. When once natural continuity has been severed in this way, if a breach is thus made between things which are by nature interconnected, it is easy to regard the phenomena that appear under these special conditions as being expressions of a special instinct that is not further reducible - the social instinct ('herd instinct', 'group mind'), which does not come to light in any other situations. But we may perhaps venture to object that it seems difficult to attribute to the factor of number a significance so great as to make it capable by itself of arousing in our mental life a new instinct that is otherwise not brought into play. Our expectation is therefore directed towards two other possibilities: that the social instinct may not be a primitive one and insusceptible of dissection, and that it may be possible to discover the beginnings of its development in a narrower circle, such as that of the family.

Although group psychology is only in its infancy, it embraces an immense number of separate issues and offers to investigators countless problems which have hitherto not even been properly distinguished from one another. The mere classification of the different forms of group formation and the description of the mental phenomena produced by them require a great expenditure of observation and exposition, and have already given rise to a copious literature. Anyone who compares the narrow dimensions of this little book with the wide extent of group psychology will at once be able to guess that only a few points chosen from the whole material are to be dealt with here. And they will in fact only be a few questions with which the depth-psychology of psycho-analysis is specially concerned.

II

LE BON'S DESCRIPTION OF THE GROUP MIND

Instead of starting from a definition, it seems more useful to begin with some indication of the range of the phenomena under review, and to select from among them a few specially striking and characteristic facts to which our enquiry can be attached. We can achieve both of these aims by means of quotation from Le Bon's deservedly famous work *Psychologie des foules*.

Let us make the matter clear once again. If a psychology, concerned with exploring the predispositions, the instinctual impulses, the motives and the aims of an individual man down to his actions and his relations with those who are nearest to him, had completely achieved its task, and had cleared up the whole of these matters with their interconnections, it would then suddenly find itself confronted by a new task which would lie before it unachieved. It would be obliged to explain the surprising fact that under a certain condition this individual, whom it had come to understand, thought, felt and acted in quite a different way from what would have been expected. And this condition is his insertion into a collection of people which has acquired the characteristic of a 'psychological group'. What, then, is a 'group'? How does it acquire the capacity for exercising such a decisive influence over the mental life of the individual? And what is the nature of the mental change which it forces upon the individual?

It is the task of a theoretical group psychology to answer these three questions. The best way of approaching them is evidently to start with the third. Observation of the changes in the individual's reactions is what provides group psychology with its material; for every attempt at an explanation must be preceded by a description of the thing that is to be explained.

I will now let Le Bon speak for himself. He says: 'The most striking peculiarity presented by a psychological group is the following. Whoever be the individuals that compose it, however like or unlike be their mode of life, their occupations, their character, or their intelligence, the fact that they have been transformed into a group puts them in possession of a sort of collective mind which makes them feel, think, and act in a manner quite different from that in which each individual of them would feel, think, and act were he in a state of isolation. There are certain ideas and feelings which do not come into being, or do not transform themselves into acts except in the case of individuals forming a group. The psychological group is a provisional being formed of heterogeneous elements, which for a moment are combined, exactly as the cells which constitute a living body form by their reunion a new being which displays characteristics very different from those possessed by each of the cells singly.' (Trans. 1920, 29.)

We shall take the liberty of interrupting Le Bon's exposition with glosses of our own, and shall accordingly insert an observation at this point. If the individuals in the group are combined into a unity, there must surely be something to unite them, and this bond might be precisely the thing that is characteristic of a group. But Le Bon does not answer this question; he goes on to consider the alteration which the individual undergoes when in a group and describes it in terms which harmonize well with the fundamental postulates of our own depth-psychology.

'It is easy to prove how much the individual forming part of a group differs from the isolated individual, but it is less easy to discover the causes of this difference.

'To obtain at any rate a glimpse of them it is necessary in the first place to call to mind the truth established by modern psychology, that unconscious phenomena play an altogether preponderating part not only in organic life, but also in the operations of the intelligence. The conscious life of the mind is of small importance in comparison with its unconscious life. The most subtle analyst, the most acute observer, is scarcely successful in discovering more than a very small number of the conscious motives that determine his conduct. Our conscious acts are the outcome of an unconscious substratum created in the mind mainly by hereditary influences. This substratum consists of the innumerable common characteristics handed down from generation to generation, which constitute the genius of a race. Behind the avowed causes of our acts there undoubtedly lie secret causes that we do not avow, but behind these secret causes there are many others more secret still, of which we ourselves are ignorant. The greater part of our daily actions are the result of hidden motives which escape our observation.' (Ibid., 30.)

Le Bon thinks that the particular acquirements of individuals become obliterated in a group, and that in this way their distinctiveness vanishes. The racial unconscious emerges; what is heterogeneous is submerged in what is homogeneous. As we should say, the mental superstructure, the development of which in individuals shows such dissimilarities, is removed, and the unconscious foundations, which are similar in everyone, stand exposed to view.

In this way individuals in a group would come to show an average character. But Le Bon believes that they also display new characteristics which they have not previously possessed, and he seeks the reason for this in three different factors.

'The first is that the individual forming part of a group acquires, solely from numerical considerations, a sentiment of invincible power which allows him to yield to instincts which, had he been alone, he would perforce have kept under restraint. He will be the less disposed to check himself, from the consideration that, a group being anonymous and in consequence irresponsible, the sentiment of responsibility which always controls individuals disappears entirely.' (Ibid., 33.)

From our point of view we need not attribute so much importance to the appearance of new characteristics. For us it would be enough to say that in a group the individual is brought under conditions which allow him to throw off the repressions of his unconscious instinctual impulses. The apparently new characteristics which he then displays are in fact the manifestations of this unconscious, in which all that is evil in the human mind is contained as a predisposition. We can find no difficulty in understanding the disappearance of conscience or of a sense of responsibility in these circumstances. It has long been our contention that 'social anxiety' is the essence of what is called conscience.¹

¹ There is some difference between Le Bon's view and ours owing to his concept of the unconscious not quite coinciding with the one adopted by psycho-analysis. Le Bon's unconscious more especially contains the most deeply buried features of the racial mind, which as a matter of fact lies outside the scope of psycho-analysis. We do not fail to recognize, indeed, that the ego's nucleus, which comprises the 'archaic heritage' of the human mind, is unconscious; but in addition to this we distinguish the 'unconscious repressed', which arose from a portion of that heritage. This concept of the repressed is not to be found in Le Bon.

'The second cause, which is contagion, also intervenes to determine the manifestation in groups of their special characteristics, and at the same time the trend they are to take. Contagion is a phenomenon of which it is easy to establish the presence, but which it is not easy to explain. It must be classed among those phenomena of a hypnotic order, which we shall shortly study. In a group every sentiment and act is contagious, and contagious to such a degree that an individual readily sacrifices his personal interest to the collective interest. This is an aptitude very contrary to his nature, and of which a man is scarcely capable, except when he makes part of a group.' (Ibid., 33.)

We shall later on base an important conjecture upon this last statement.

'A third cause, and by far the most important, determines in the individuals of a group special characteristics which are quite contrary at times to those presented by the isolated individual. I allude to that suggestibility of which, moreover, the contagion mentioned above is only an effect.

'To understand this phenomenon it is necessary to bear in mind certain recent physiological discoveries. We know to-day that by various processes an individual may be brought into such a condition that, having entirely lost his conscious personality, he obeys all the suggestions of the operator who has deprived him of it, and commits acts in utter contradiction with his character and habits. The most careful investigations seem to prove that an individual immersed for some length of time in a group in action soon finds himself - either in consequence of the magnetic influence given out by the group, or from some other cause of which we are ignorant - in a special state, which much resembles the state of "fascination" in which the hypnotized individual finds himself in the hands of the hypnotizer. . . . The conscious personality has entirely vanished; will and discernment are lost. All feelings and thoughts are bent in the direction determined by the hypnotizer.

'Such also is approximately the state of the individual forming part of a psychological group. He is no longer conscious of his acts. In his case, as in the case of the hypnotized subject, at the same time that certain faculties are destroyed, others may be brought to a high degree of exaltation. Under the influence of a suggestion, he will undertake the accomplishment of certain acts with irresistible impetuosity. This impetuosity is the more irresistible in the case of groups than in that of the hypnotized subject, from the fact that, the suggestion being the same for all the individuals in the group, it gains in strength by reciprocity.' (Ibid., 34.)

'We see, then, that the disappearance of the conscious personality, the predominance of the unconscious personality, the turning by means of suggestion and contagion of feelings and ideas in an identical direction, the tendency to immediately transform the suggested ideas into acts; these, we see, are the principal characteristics of the individual forming part of a group. He is no longer himself, but has become an automaton who has ceased to be guided by his will.' (Ibid., 35.)

I have quoted this passage so fully in order to make it quite clear that Le Bon explains the condition of an individual in a group as being actually hypnotic, and does not merely make a comparison between the two states. We have no intention of raising any objection at this point, but wish only to emphasize the fact that the two last causes of an individual becoming altered in a group (the contagion and the heightened suggestibility) are evidently not on a par, since the contagion seems actually to be a manifestation of the suggestibility. Moreover the effects of the two factors do not seem to be sharply differentiated in the text of Le Bon's remarks. We may perhaps best interpret his statement if we connect the contagion with the effects of the individual members of the group on one another, while we point to another source for those manifestations of suggestion in the group which he regards as similar to the phenomena of hypnotic influence. But to what source? We cannot avoid being struck with a sense of deficiency when we notice that one of the chief elements of the comparison, namely the person who is to replace the hypnotist in the case of the group, is not mentioned in Le Bon's exposition. But he nevertheless distinguishes between this influence of 'fascination' which remains plunged in obscurity and the contagious effect which the individuals exercise upon one another and by which the original suggestion is strengthened.

Here is yet another important consideration for helping us to understand the individual in a group: 'Moreover, by the mere fact that he forms part of an organized group, a man descends several rungs in the ladder of civilization. Isolated, he may be a cultivated individual; in a crowd, he is a barbarian - that is, a creature acting by instinct. He possesses the spontaneity, the violence, the ferocity, and also the enthusiasm and heroism of primitive beings.' (Ibid., 36.) Le Bon then dwells especially upon the lowering in intellectual ability which an individual experiences when he becomes merged in a group.¹

Let us now leave the individual, and turn to the group mind, as it has been outlined by Le Bon. It shows not a single feature which a psycho-analyst would find any difficulty in placing or in deriving from its source. Le Bon himself shows us the way by pointing to its similarity with the mental life of primitive people and of children (ibid., 40).

A group is impulsive, changeable and irritable. It is led almost exclusively by the unconscious.² The impulses which a group obeys may according to circumstances be generous or cruel, heroic or cowardly, but they are always so imperious that no personal interest, not even that of self-preservation, can make itself felt (ibid., 41). Nothing about it is premeditated. Though it may desire things passionately, yet this is never so for long, for it is incapable of perseverance. It cannot tolerate any delay between its desire and the fulfilment of what it desires. It has a sense of omnipotence; the notion of impossibility disappears for the individual in a group.³

¹ Compare Schiller's couplet:

Jeder, sieht man ihn einzeln, ist leidlich klug und verständig;

Sind sie in corpore, gleich wird euch ein Dummkopf daraus.

² 'Unconscious' is used here correctly by Le Bon in the descriptive sense, where it does not mean only the 'repressed'.

³ Compare the third essay in my *Totem and Taboo* (1912-13).

A group is extraordinarily credulous and open to influence, it has no critical faculty, and the improbable does not exist for it. It thinks in images, which call one another up by association (just as they arise with individuals in states of free imagination), and whose agreement with reality is never checked by any reasonable agency. The feelings of a group are always very simple and very exaggerated. So that a group knows neither doubt nor uncertainty.¹

It goes directly to extremes; if a suspicion is expressed, it is instantly changed into an incontrovertible certainty; a trace of antipathy is turned into furious hatred (*ibid.*, 56).²

Inclined as it itself is to all extremes, a group can only be excited by an excessive stimulus. Anyone who wishes to produce an effect upon it needs no logical adjustment in his arguments; he must paint in the most forcible colours, he must exaggerate, and he must repeat the same thing again and again.

Since a group is in no doubt as to what constitutes truth or error, and is conscious, moreover, of its own great strength, it is as intolerant as it is obedient to authority. It respects force and can only be slightly influenced by kindness, which it regards merely as a form of weakness. What it demands of its heroes is strength, or even violence. It wants to be ruled and oppressed and to fear its masters. Fundamentally it is entirely conservative and it has a deep aversion to all innovations and advances and an unbounded respect for tradition (*ibid.*, 62).

¹ In the interpretation of dreams, to which, indeed, we owe our best knowledge of unconscious mental life, we follow a technical rule of disregarding doubt and uncertainty in the narrative of the dream, and of treating every element of the manifest dream as being quite certain. We attribute doubt and uncertainty to the influence of the censorship to which the dream-work is subjected, and we assume that the primary dream-thoughts are not acquainted with doubt and uncertainty as critical processes. They may of course be present, like anything else, as part of the content of the day's residues which lead to the dream.

² The same extreme and unmeasured intensification of every emotion is also a feature of the affective life of children, and it is present as well in dream life. Thanks to the isolation of the single emotions in the unconscious, a slight annoyance during the day will express itself in a dream as a wish for the offending person's death, or a breath of temptation may give the impetus to the portrayal in the dream of a criminal action. Hanns Sachs has made an appropriate remark on this point: 'If we look in our consciousness at something that has been told us by a dream about a contemporary (real) situation, we ought not to be surprised to find that the monster which we saw under the magnifying glass of analysis turns out to be a tiny infusorian.'

In order to make a correct judgement upon the morals of groups, one must take into consideration the fact that when individuals come together in a group all their individual inhibitions fall away and all the cruel, brutal and destructive instincts, which lie dormant in individuals as relics of a primitive epoch, are stirred up to find free gratification. But under the influence of suggestion groups are also capable of high achievements in the shape of abnegation, unselfishness, and devotion to an ideal. While with isolated individuals personal interest is almost the only motive force, with groups it is very rarely prominent. It is possible to speak of an individual having his moral standards raised by a group (ibid., 65). Whereas the intellectual capacity of a group is always far below that of an individual, its ethical conduct may rise as high above his as it may sink deep below it.

Some other features in Le Bon's description show in a clear light how well justified is the identification of the group mind with the mind of primitive people. In groups the most contradictory ideas can exist side by side and tolerate each other, without any conflict arising from the logical contradiction between them. But this is also the case in the unconscious mental life of individuals, of children and of neurotics, as psycho-analysis has long pointed out.¹

¹ In young children, for instance, ambivalent emotional attitudes towards those who are nearest to them exist side by side for a long time, without either of them interfering with the expression of the other and opposite one. If eventually a conflict breaks out between the two, it is often settled by the child making a change of object and displacing one of the ambivalent emotions on to a substitute. The history of the development of a neurosis in an adult will also show that a suppressed emotion may frequently persist for a long time in unconscious or even in conscious phantasies, the content of which naturally runs directly counter to some predominant tendency, and yet that this opposition does not result in any proceedings on the part of the ego against what it has repudiated. The phantasy is tolerated for quite a long time, until suddenly one day, usually as a result of an increase in the affective cathexis of the phantasy, a conflict breaks out between it and the ego with all the usual consequences. In the process of a child's development into a mature adult there is a more and more extensive integration of his personality, a co-ordination of the separate instinctual impulses and purposive trends which have grown up in him independently of one another. The analogous process in the domain of sexual life has long been known to us as the co-ordination of all the sexual instincts into a definitive genital organization. (*Three Essays on the Theory of Sexuality*, 1905d.) Moreover, that the unification of the ego is liable to the same interferences as that of the libido is shown by numerous familiar instances, such as that of men of science who have preserved their faith in the Bible, and other similar cases. - The various possible ways in which the ego can later disintegrate form a special chapter in psychopathology.

A group, further, is subject to the truly magical power of words; they can evoke the most formidable tempests in the group mind, and are also capable of stilling them (ibid., 117). 'Reason and arguments are incapable of combating certain words and formulas. They are uttered with solemnity in the presence of groups, and as soon as they have been pronounced an expression of respect is visible on every countenance, and all heads are bowed. By many they are considered as natural forces or as supernatural powers.' (ibid., 117). It is only necessary in this connection to remember the taboo upon names among primitive people and the magical powers which they ascribe to names and words.¹

And, finally, groups have never thirsted after truth. They demand illusions, and cannot do without them. They constantly give what is unreal precedence over what is real; they are almost as strongly influenced by what is untrue as by what is true. They have an evident tendency not to distinguish between the two (ibid., 77).

We have pointed out that this predominance of the life of phantasy and of the illusion born of an unfulfilled wish is the ruling factor in the psychology of neuroses. We have found that what neurotics are guided by is not ordinary objective reality but psychological reality. A hysterical symptom is based upon phantasy instead of upon the repetition of real experience, and the sense of guilt in an obsessional neurosis is based upon the fact of an evil intention which was never carried out. Indeed, just as in dreams and in hypnosis, in the mental operations of a group the function for testing the reality of things falls into the background in comparison with the strength of wishful impulses with their affective cathexis.

¹ See *Totem and Taboo* (1912-13).

What Le Bon says on the subject of leaders of groups is less exhaustive, and does not enable us to make out an underlying principle so clearly. He thinks that as soon as living beings are gathered together in certain numbers, no matter whether they are a herd of animals or a collection of human beings, they place themselves instinctively under the authority of a chief (*ibid.*, 134). A group is an obedient herd, which could never live without a master. It has such a thirst for obedience that it submits instinctively to anyone who appoints himself its master.

Although in this way the needs of a group carry it half-way to meet the leader, yet he too must fit in with it in his personal qualities. He must himself be held in fascination by a strong faith (in an idea) in order to awaken the group's faith; he must possess a strong and imposing will, which the group, which has no will of its own, can accept from him. Le Bon then discusses the different kinds of leaders, and the means by which they work upon the group. On the whole he believes that the leaders make themselves felt by means of the ideas in which they themselves are fanatical believers.

Moreover, he ascribes both to the ideas and to the leaders a mysterious and irresistible power, which he calls 'prestige'. Prestige is a sort of domination exercised over us by an individual, a work or an idea. It entirely paralyses our critical faculty, and fills us with wonderment and respect. It would seem to arouse a feeling like that of 'fascination' in hypnosis (*ibid.*, 148). He distinguishes between acquired or artificial and personal prestige. The former is attached to persons in virtue of their name, fortune and reputation, and to opinions, works of art, etc., in virtue of tradition. Since in every case it harks back to the past, it cannot be of much help to us in understanding this puzzling influence. Personal prestige is attached to a few people, who become leaders by means of it, and it has the effect of making everyone obey them as though by the operation of some magnetic magic. All prestige, however, is also dependent upon success, and is lost in the event of failure (*ibid.*, 159).

Le Bon does not give the impression of having succeeded in bringing the function of the leader and the importance of prestige completely into harmony with his brilliantly executed picture of the group mind.

III

OTHER ACCOUNTS OF COLLECTIVE MENTAL LIFE

We have made use of Le Bon's description by way of introduction, because it fits in so well with our own psychology in the emphasis which it lays upon unconscious mental life. But we must now add that as a matter of fact none of that author's statements bring forward anything new. Everything that he says to the detriment and depreciation of the manifestations of the group mind had already been said by others before him with equal distinctness and equal hostility, and has been repeated in unison by thinkers, statesmen and writers since the earliest periods of literature.¹ The two theses which comprise the most important of Le Bon's opinions, those touching upon the collective inhibition of intellectual functioning and the heightening of affectivity in groups, had been formulated shortly before by Sighele.² At bottom, all that is left over as being peculiar to Le Bon are the two notions of the unconscious and of the comparison with the mental life of primitive people, and even these had naturally often been alluded to before him.

But, what is more, the description and estimate of the group mind as they have been given by Le Bon and the rest have not by any means been left undisputed. There is no doubt that all the phenomena of the group mind which have just been mentioned have been correctly observed, but it is also possible to distinguish other manifestations of group formation, which operate in a precisely opposite sense, and from which a much higher opinion of the group mind must necessarily follow.

Le Bon himself was prepared to admit that in certain circumstances the morals of a group can be higher than those of the individuals that compose it, and that only collectivities are capable of a high degree of unselfishness and devotion. 'While with isolated individuals personal interest is almost the only motive force, with groups it is very rarely prominent.' (Le Bon, trans. 1920, 65.) Other writers adduce the fact that it is only society which prescribes any ethical standards at all for the individual, while he as a rule fails in one way or another to come up to its high demands. Or they point out that in exceptional circumstances there may arise in communities the phenomenon of enthusiasm, which has made the most splendid group achievements possible.

¹ See Kraskovic (1915), particularly the bibliography.

² See Moede (1915).

As regards intellectual work it remains a fact, indeed, that great decisions in the realm of thought and momentous discoveries and solutions of problems are only possible to an individual working in solitude. But even the group mind is capable of creative genius in the field of intelligence, as is shown above all by language itself, as well as by folk-song, folklore and the like. It remains an open question, moreover, how much the individual thinker or writer owes to the stimulation of the group in which he lives, and whether he does more than perfect a mental work in which the others have had a simultaneous share.

In face of these completely contradictory accounts, it looks as though the work of group psychology were bound to come to an ineffectual end. But it is easy to find a more hopeful escape from the dilemma. A number of very different structures have probably been merged under the term 'group' and may require to be distinguished. The assertions of Sighele, Le Bon and the rest relate to groups of a short-lived character, which some passing interest has hastily agglomerated out of various sorts of individuals. The characteristics of revolutionary groups, and especially those of the great French Revolution, have unmistakably influenced their descriptions. The opposite opinions owe their origin to the consideration of those stable groups or associations in which mankind pass their lives, and which are embodied in the institutions of society. Groups of the first kind stand in the same sort of relation to those of the second as a high but choppy sea to a ground swell.

McDougall, in his book on *The Group Mind* (1920a), starts out from the same contradiction that has just been mentioned, and finds a solution for it in the factor of organization. In the simplest case, he says, the 'group' possesses no organization at all or one scarcely deserving the name. He describes a group of this kind as a 'crowd'. But he admits that a crowd of human beings can hardly come together without possessing at all events the rudiments of an organization, and that precisely in these simple groups some fundamental facts of collective psychology can be observed with special ease (McDougall, 1920a, 22). Before the members of a random crowd of people can constitute something like a group in the psychological sense, a condition has to be fulfilled: these individuals must have something in common with one another, a common interest in an object, a similar emotional bias in some situation or other, and ('consequently', I should like to interpolate) 'some degree of reciprocal influence' (ibid., 23). The higher the degree of 'this mental homogeneity', the more readily do the individuals form a psychological group, and the more striking are the manifestations of a group mind.

The most remarkable and also the most important result of the formation of a group is the 'exaltation or intensification of emotion' produced in every member of it (ibid., 24). In McDougall's opinion men's emotions are stirred in a group to a pitch that they seldom or never attain under other conditions; and it is a pleasurable experience for those who are concerned, to surrender themselves so unreservedly to their passions and thus to become merged in the group and to lose the sense of the limits of their individuality. The manner in which individuals are thus carried away by a common impulse is explained by McDougall by means of what he calls the 'principle of direct induction of emotion by way of the primitive sympathetic response' (ibid., 25), that is, by means of the emotional contagion with which we are already familiar. The fact is that the perception of the signs of an affective state is calculated automatically to arouse the same affect in the person who perceives them. The greater the number of people in whom the same affect can be simultaneously observed, the stronger does this automatic compulsion grow. The individual loses his power of criticism, and lets himself slip into the same affect. But in so doing he increases the excitement of the other people, who had produced this result in him, and thus the affective charge of the individuals becomes intensified by mutual interaction. Something is unmistakably at work in the nature of a compulsion to do the same as the others, to remain in harmony with the many. The cruder and simpler emotional impulses are the more apt to spread through a group in this way (ibid., 39).

This mechanism for the intensification of affect is favoured by some other influences which emanate from groups. A group impresses the individual as being an unlimited power and an insurmountable peril. For the moment it replaces the whole of human society, which is the wielder of authority, whose punishments the individual fears, and for whose sake he has submitted to so many inhibitions. It is clearly perilous for him to put himself in opposition to it, and it will be safer to follow the example of those around him and perhaps even 'hunt with the pack'. In obedience to the new authority he may put his former 'conscience' out of action, and so surrender to the attraction of the increased pleasure that is certainly obtained from the removal of inhibitions. On the whole, therefore, it is not so remarkable that we should see an individual in a group doing or approving things which he would have avoided in the normal conditions of life; and in this way we may even hope to clear up a little of the obscurity which is so often covered by the enigmatic word 'suggestion'.

McDougall does not dispute the thesis as to the collective inhibition of intelligence in groups (ibid., 41). He says that the minds of lower intelligence bring down those of a higher order to their own level. The latter are obstructed in their activity, because in general an intensification of affect creates unfavourable conditions for sound intellectual work, and further because the individuals are intimidated by the group and their mental activity is not free, and because there is a lowering in each individual of his sense of responsibility for his own performances.

The judgement with which McDougall sums up the psychological behaviour of a simple 'unorganized' group is no more friendly than that of Le Bon. Such a group 'is excessively emotional, impulsive, violent, fickle, inconsistent, irresolute and extreme in action, displaying only the coarser emotions and the less refined sentiments; extremely suggestible, careless in deliberation, hasty in judgement, incapable of any but the simpler and imperfect forms of reasoning; easily swayed and led, lacking in self-consciousness, devoid of self-respect and of sense of responsibility, and apt to be carried away by the consciousness of its own force, so that it tends to produce all the manifestations we have learnt to expect of any irresponsible and absolute power. Hence its behaviour is like that of an unruly child or an untutored passionate savage in a strange situation, rather than like that of its average member; and in the worst cases it is like that of a wild beast, rather than like that of human beings.' (ibid., 45.)

Since McDougall contrasts the behaviour of a highly organized group with what has just been described, we shall be particularly interested to learn in what this organization consists, and by what factors it is produced. The author enumerates five 'principal conditions' for raising collective mental life to a higher level.

The first and fundamental condition is that there should be some degree of continuity of existence in the group. This may be either material or formal: material, if the same individuals persist in the group for some time; and formal, if there is developed within the group a system of fixed positions which are occupied by a succession of individuals.

The second condition is that in the individual member of the group some definite idea should be formed of the nature, composition, functions and capacities of the group, so that from this he may develop an emotional relation to the group as a whole.

The third is that the group should be brought into interaction (perhaps in the form of rivalry) with other groups similar to it but differing from it in many respects.

The fourth is that the group should possess traditions, customs and habits, and especially such as determine the relations of its members to one another.

The fifth is that the group should have a definite structure, expressed in the specialization and differentiation of the functions of its constituents.

According to McDougall, if these conditions are fulfilled, the psychological disadvantages of group formations are removed. The collective lowering of intellectual ability is avoided by withdrawing the performance of intellectual tasks from the group and reserving them for individual members of it.

It seems to us that the condition which McDougall designates as the 'organization' of a group can with more justification be described in another way. The problem consists in how to procure for the group precisely those features which were characteristic of the individual and which are extinguished in him by the formation of the group. For the individual, outside the primitive group, possessed his own continuity, his self-consciousness, his traditions and customs, his own particular functions and position, and he kept apart from his rivals. Owing to his entry into an 'unorganized' group he had lost this distinctiveness for a time. If we thus recognize that the aim is to equip the group with the attributes of the individual, we shall be reminded of a valuable remark of Trotter's,¹ to the effect that the tendency towards the formation of groups is biologically a continuation of the multicellular character of all the higher organisms.²

¹ *Instincts of the Herd in Peace and War* (1916)

² I differ from what is in other respects an understanding and shrewd criticism by Hans Kelsen (1922) when he says that to provide the 'group mind' with an organization of this kind signifies a hypostasis of it - that is to say, implies an attribution to it of independence of the mental processes in the individual.

IV

SUGGESTION AND LIBIDO

We started from the fundamental fact that an individual in a group is subjected through its influence to what is often a profound alteration in his mental activity. His liability to affect becomes extraordinarily intensified, while his intellectual ability is markedly reduced, both processes being evidently in the direction of an approximation to the other individuals in the group; and this result can only be reached by the removal of those inhibitions upon his instincts which are peculiar to each individual, and by his resigning those expressions of his inclinations which are especially his own. We have heard that these often unwelcome consequences are to some extent at least prevented by a higher 'organization' of the group; but this does not contradict the fundamental fact of group psychology - the two theses as to the intensification of the affects and the inhibition of the intellect in primitive groups. Our interest is now directed to discovering the psychological explanation of this mental change which is experienced by the individual in a group.

It is clear that rational factors (such as the intimidation of the individual which has already been mentioned, that is, the action of his instinct of self-preservation) do not cover the observable phenomena. Beyond this what we are offered as an explanation by authorities on sociology and group psychology is always the same, even though it is given various names, and that is the magic word 'suggestion'. Tarde calls it 'imitation'; but we cannot help agreeing with a writer who protests that imitation comes under the concept of suggestion, and is in fact one of its results (Brugell, 1913). Le Bon traces back all the puzzling features of social phenomena to two factors: the mutual suggestion of individuals and the prestige of leaders. But prestige, again, is only recognizable by its capacity for evoking suggestion. McDougall for a moment gives us an impression that his principle of 'primitive induction of emotion' might enable us to do without the assumption of suggestion. But on further consideration we are forced to perceive that this principle makes no more than the familiar assertions about 'imitation' or 'contagion', except for a decided stress upon the emotional factor. There is no doubt that something exists in us which, when we become aware of signs of an emotion in someone else, tends to make us fall into the same emotion; but how often do we not successfully oppose it, resist the emotion, and react in quite an opposite way? Why, therefore, do we invariably give way to this contagion when we are in a group? Once more we should have to say that what compels us to obey this tendency is imitation, and what induces the emotion in us is the group's suggestive influence. Moreover, quite apart from this, McDougall does not enable us to evade suggestion; we hear from him as well as from other writers that groups are distinguished by their special suggestibility.

We shall therefore be prepared for the statement that suggestion (or more correctly suggestibility) is actually an irreducible, primitive phenomenon, a fundamental fact in the mental life of man. Such, too, was the opinion of Bernheim, of whose astonishing arts I was a witness in the year 1889. But I can remember even then feeling a muffled hostility to this tyranny of suggestion. When a patient who showed himself unamenable was met with the shout: 'What are you doing? *Vous vous contre-suggestionnez!*', I said to myself that this was an evident injustice and an act of violence. For the man certainly had a right to counter-suggestions if people were trying to subdue him with suggestions. Later on my resistance took the direction of protesting against the view that suggestion, which explained everything, was itself to be exempt from explanation. Thinking of it, I repeated the old conundrum:¹

Christoph trug Christum,
Christus trug die ganze Welt,
Sag' wo hat Christoph
Damals hin den Fuss gestellt?

Christophorus Christum, sed Christus sustulit orbem:
Constiterit pedibus dic ubi Christophorus?

¹ Konrad Richter, 'Der deutsche S. Christoph.'

Now that I once more approach the riddle of suggestion after having kept away from it for some thirty years, I find there is no change in the situation. (There is one exception to be made to this statement, and one which bears witness precisely to the influence of psycho-analysis.) I notice that particular efforts are being made to formulate the concept of suggestion correctly, that is, to fix the conventional use of the name (e.g. McDougall, 1920*b*). And this is by no means superfluous, for the word is acquiring a more and more extended use and a looser and looser meaning, and will soon come to designate any sort of influence whatever, just as it does in English, where 'to suggest' and 'suggestion' correspond to our *nahelegen* and *Anregung*. But there has been no explanation of the nature of suggestion, that is, of the conditions under which influence without adequate logical foundation takes place. I should not avoid the task of supporting this statement by an analysis of the literature of the last thirty years, if I were not aware that an exhaustive enquiry is being undertaken close at hand which has in view the fulfilment of this very task.¹

Instead of this I shall make an attempt at using the concept of *libido* for the purpose of throwing light upon group psychology, a concept which has done us such good service in the study of psychoneuroses.

Libido is an expression taken from the theory of the emotions. We call by that name the energy, regarded as a quantitative magnitude (though not at present actually measurable), of those instincts which have to do with all that may be comprised under the word 'love'. The nucleus of what we mean by love naturally consists (and this is what is commonly called love, and what the poets sing of) in sexual love with sexual union as its aim. But we do not separate from this - what in any case has a share in the name 'love' - on the one hand, self-love, and on the other, love for parents and children, friendship and love for humanity in general, and also devotion to concrete objects and to abstract ideas. Our justification lies in the fact that psycho-analytic research has taught us that all these tendencies are an expression of the same instinctual impulses; in relations between the sexes these impulses force their way towards sexual union, but in other circumstances they are diverted from this aim or are prevented from reaching it, though always preserving enough of their original nature to keep their identity recognizable (as in such features as the longing for proximity, and self-sacrifice).

¹ This work has unfortunately not materialized.

We are of opinion, then, that language has carried out an entirely justifiable piece of unification in creating the word 'love' with its numerous uses, and that we cannot do better than take it as the basis of our scientific discussions and expositions as well. By coming to this decision, psycho-analysis has let loose a storm of indignation, as though it had been guilty of an act of outrageous innovation. Yet it has done nothing original in taking love in this 'wider' sense. In its origin, function, and relation to sexual love, the 'Eros' of the philosopher Plato coincides exactly with the love-force, the libido of psycho-analysis, as has been shown in detail by Nachansohn (1915) and Pfister (1921); and when the apostle Paul, in his famous epistle to the Corinthians, praises love above all else, he certainly understands it in the same 'wider' sense.¹ But this only shows that men do not always take their great thinkers seriously, even when they profess most to admire them.

Psycho-analysis, then, gives these love instincts the name of sexual instincts, *a potiori* and by reason of their origin. The majority of 'educated' people have regarded this nomenclature as an insult, and have taken their revenge by retorting upon psycho-analysis with the reproach of 'pan-sexualism'. Anyone who considers sex as something mortifying and humiliating to human nature is at liberty to make use of the more genteel expressions 'Eros' and 'erotic'. I might have done so myself from the first and thus have spared myself much opposition. But I did not want to, for I like to avoid concessions to faintheartedness. One can never tell where that road may lead one; one gives way first in words, and then little by little in substance too. I cannot see any merit in being ashamed of sex; the Greek word 'Eros', which is to soften the affront, is in the end nothing more than a translation of our German word *Liebe*; and finally, he who knows how to wait need make no concessions.

¹ 'Though I speak with the tongues of men and of angels, and have not charity, I am become as sounding brass, or a tinkling cymbal.'

We will try our fortune, then, with the supposition that love relationships (or, to use a more neutral expression, emotional ties) also constitute the essence of the group mind. Let us remember that the authorities make no mention of any such relations. What would correspond to them is evidently concealed behind the shelter, the screen, of suggestion. Our hypothesis finds support in the first instance from two passing thoughts. First, that a group is clearly held together by a power of some kind: and to what power could this feat be better ascribed than to Eros, which holds together everything in the world? Secondly, that if an individual gives up his distinctiveness in a group and lets its other members influence him by suggestion, it gives one the impression that he does it because he feels the need of being in harmony with them rather than in opposition to them - so that perhaps after all he does it '*ihnen zu Liebe*'.

V

TWO ARTIFICIAL GROUPS: THE CHURCH AND THE ARMY

We may recall from what we know of the morphology of groups that it is possible to distinguish very different kinds of groups and opposing lines in their development. There are very fleeting groups and extremely lasting ones; homogeneous ones, made up of the same sorts of individuals, and unhomogeneous ones; natural groups, and artificial ones, requiring an external force to keep them together; primitive groups, and highly organized ones with a definite structure. But for reasons which remain to be explained we should like to lay particular stress upon a distinction to which writers on the subject have been inclined to give too little attention; I refer to that between leaderless groups and those with leaders. And, in complete opposition to the usual practice, we shall not choose a relatively simple group formation as our point of departure, but shall begin with highly organized, lasting and artificial groups. The most interesting example of such structures are Churches - communities of believers - and armies.

A Church and an army are artificial groups - that is, a certain external force is employed to prevent them from disintegrating¹ and to check alterations in their structure. As a rule a person is not consulted, or is given no choice, as to whether he wants to enter such a group; any attempt at leaving it is usually met with persecution or with severe punishment, or has quite definite conditions attached to it. It is quite outside our present interest to enquire why these associations need such special safeguards. We are only attracted by one circumstance, namely that certain facts, which are far more concealed in other cases, can be observed very clearly in those highly organized groups which are protected from dissolution in the manner that has been mentioned.

¹ In groups, the attributes 'stable' and 'artificial' seem to coincide or at least to be intimately connected.

In a Church (and we may with advantage take the Catholic Church as a type) as well as in an army, however different the two may be in other respects, the same illusion holds good of there being a head - in the Catholic Church Christ, in an army its Commander-in-Chief - who loves all the individuals in the group with an equal love. Everything depends upon this illusion; if it were to be dropped, then both Church and army would dissolve, so far as the external force permitted them to. This equal love was expressly enunciated by Christ: 'Inasmuch as ye have done it unto one of the least of these my brethren, ye have done it unto me.' He stands to the individual members of the group of believers in the relation of a kind elder brother; he is their substitute father. All the demands that are made upon the individual are derived from this love of Christ's. A democratic strain runs through the Church, for the very reason that before Christ everyone is equal, and that everyone has an equal share in his love. It is not without a deep reason that the similarity between the Christian community and a family is invoked, and that believers call themselves brothers in Christ, that is, brothers through the love which Christ has for them. There is no doubt that the tie which unites each individual with Christ is also the cause of the tie which unites them with one another. The like holds good of an army. The Commander-in-Chief is a father who loves all soldiers equally, and for that reason they are comrades among themselves. The army differs structurally from the Church in being built up of a series of such groups. Every captain is, as it were, the Commander-in-Chief and the father of his company, and so is every non-commissioned officer of his section. It is true that a similar hierarchy has been constructed in the Church, but it does not play the same part in it economically; for more knowledge and care about individuals may be attributed to Christ than to a human Commander-in-Chief.

An objection will justly be raised against this conception of the libidinal structure of an army on the ground that no place has been found in it for such ideas as those of one's country, of national glory, etc., which are of such importance in holding an army together. The answer is that that is a different instance of a group tie, and no longer such a simple one; for the examples of great generals, like Caesar, Wallenstein, or Napoleon, show that such ideas are not indispensable to the existence of an army. We shall presently touch upon the possibility of a leading idea being substituted for a leader and upon the relations between the two. The neglect of this libidinal factor in an army, even when it is not the only factor operative, seems to be not merely a theoretical omission but also a practical danger. Prussian militarism, which was just as unpsychological as German science, may have had to suffer the consequences of this in the World War. We know that the war neuroses which ravaged the German army have been recognized as being a protest of the individual against the part he was expected to play in the army; and according to the communication of Simmel (1918), the hard treatment of the men by their superiors may be considered as foremost among the motive forces of the disease. If the importance of the libido's claims on this score had been better appreciated, the fantastic promises of the American President's Fourteen Points would probably not have been believed so easily, and the splendid instrument would not have broken in the hands of the German leaders.

It is to be noticed that in these two artificial groups each individual is bound by libidinal ties on the one hand to the leader (Christ, the Commander-in-Chief) and on the other hand to the other members of the group. How these two ties are related to each other, whether they are of the same kind and the same value, and how they are to be described psychologically - these questions must be reserved for subsequent enquiry. But we shall venture even now upon a mild reproach against earlier writers for not having sufficiently appreciated the importance of the leader in the psychology of the group, while our own choice of this as a first subject for investigation has brought us into a more favourable position. It would appear as though we were on the right road towards an explanation of the principal phenomenon of group psychology - the individual's lack of freedom in a group. If each individual is bound in two directions by such an intense emotional tie, we shall find no difficulty in attributing to that circumstance the alteration and limitation which have been observed in his personality.

A hint to the same effect, that the essence of a group lies in the libidinal ties existing in it, is also to be found in the phenomenon of panic, which is best studied in military groups. A panic arises if a group of that kind becomes disintegrated. Its characteristics are that none of the orders given by superiors are any longer listened to, and that each individual is only solicitous on his own account, and without any consideration for the rest. The mutual ties have ceased to exist, and a gigantic and senseless fear is set free. At this point, again, the objection will naturally be made that it is rather the other way round; and that the fear has grown so great as to be able to disregard all ties and all feelings of consideration for others. McDougall (1920a, 24) has even made use of panic (though not of military panic) as a typical instance of that intensification of emotion by contagion ('primary induction') on which he lays so much emphasis. But nevertheless this rational method of explanation is here quite inadequate. The very question that needs explanation is why the fear has become so gigantic. The greatness of the danger cannot be responsible, for the same army which now falls a victim to panic may previously have faced equally great or greater danger with complete success; it is of the very essence of panic that it bears no relation to the danger that threatens, and often breaks out on the most trivial occasions. If an individual in panic fear begins to be solicitous only on his own account, he bears witness in so doing to the fact that the emotional ties, which have hitherto made the danger seem small to him, have ceased to exist. Now that he is by himself in facing the danger, he may surely think it greater. The fact is, therefore, that panic fear presupposes a relaxation in the libidinal structure of the group and reacts to that relaxation in a justifiable manner, and the contrary view - that the libidinal ties of the group are destroyed owing to fear in the face of the danger - can be refuted.

The contention that fear in a group is increased to enormous proportions through induction (contagion) is not in the least contradicted by these remarks. McDougall's view meets the case entirely when the danger is a really great one and when the group has no strong emotional ties - conditions which are fulfilled, for instance, when a fire breaks out in a theatre or a place of amusement. But the truly instructive case and the one which can be best employed for our purposes is that mentioned above, in which a body of troops breaks into a panic although the danger has not increased beyond a degree that is usual and has often been previously faced. It is not to be expected that the usage of the word 'panic' should be clearly and unambiguously determined. Sometimes it is used to describe any collective fear, sometimes even fear in an individual when it exceeds all bounds, and often the name seems to be reserved for cases in which the outbreak of fear is not warranted by the occasion. If we take the word 'panic' in the sense of collective fear, we can establish a far-reaching analogy. Fear in an individual is provoked either by the greatness of a danger or by the cessation of emotional ties (libidinal cathexes); the latter is the case of neurotic fear or anxiety.¹ In just the same way panic arises either owing to an increase of the common danger or owing to the disappearance of the emotional ties which hold the group together; and the latter case is analogous to that of neurotic anxiety.²

Anyone who, like McDougall (1920a), describes a panic as one of the plainest functions of the 'group mind', arrives at the paradoxical position that this group mind does away with itself in one of its most striking manifestations. It is impossible to doubt that panic means the disintegration of a group; it involves the cessation of all the feelings of consideration which the members of the group otherwise show one another.

The typical occasion of the outbreak of a panic is very much as it is represented in Nestroy's parody of Hebbel's play about Judith and Holofernes. A soldier cries out: 'The general has lost his head!' and thereupon all the Assyrians take to flight. The loss of the leader in some sense or other, the birth of misgivings about him, brings on the outbreak of panic, though the danger remains the same; the mutual ties between the members of the group disappear, as a rule, at the same time as the tie with their leader. The group vanishes in dust, like a Prince Rupert's drop when its tail is broken off.

¹ See Lecture XXV of my *Introductory Lectures* (1916-17)

² Compare Béla von Felszeghy's interesting though somewhat over-imaginative paper 'Panik und Pankomplex' (1920).

The dissolution of a religious group is not so easy to observe. A short time ago there came into my hands an English novel of Catholic origin, recommended by the Bishop of London, with the title *When It Was Dark*. It gave a clever and, as it seems to me, a convincing picture of such a possibility and its consequences. The novel, which is supposed to relate to the present day, tells how a conspiracy of enemies of the person of Christ and of the Christian faith succeed in arranging for a sepulchre to be discovered in Jerusalem. In this sepulchre is an inscription, in which Joseph of Arimathaea confesses that for reasons of piety he secretly removed the body of Christ from its grave on the third day after its entombment and buried it in this spot. The resurrection of Christ and his divine nature are by this means disproved, and the result of this archaeological discovery is a convulsion in European civilization and an extraordinary increase in all crimes and acts of violence, which only ceases when the forgers' plot has been revealed.

The phenomenon which accompanies the dissolution that is here supposed to overtake a religious group is not fear, for which the occasion is wanting. Instead of it ruthless and hostile impulses towards other people make their appearance, which, owing to the equal love of Christ, they had previously been unable to do.¹ But even during the kingdom of Christ those people who do not belong to the community of believers, who do not love him, and whom he does not love, stand outside this tie. Therefore a religion, even if it calls itself the religion of love, must be hard and unloving to those who do not belong to it. Fundamentally indeed every religion is in this same way a religion of love for all those whom it embraces; while cruelty and intolerance towards those who do not belong to it are natural to every religion. However difficult we may find it personally, we ought not to reproach believers too severely on this account; people who are unbelieving or indifferent are much better off psychologically in this matter. If to-day that intolerance no longer shows itself so violent and cruel as in former centuries, we can scarcely conclude that there has been a softening in human manners. The cause is rather to be found in the undeniable weakening of religious feelings and the libidinal ties which depend upon them. If another group tie takes the place of the religious one - and the socialistic tie seems to be succeeding in doing so - then there will be the same intolerance towards outsiders as in the age of the Wars of Religion; and if differences between scientific opinions could ever attain a similar significance for groups, the same result would again be repeated with this new motivation.

¹ Compare the explanation of similar phenomena after the abolition of the paternal authority of the sovereign given in Federn's *Die vaterlose Gesellschaft* (1919).

VI

FURTHER PROBLEMS AND LINES OF WORK

We have hitherto considered two artificial groups and have found that both are dominated by emotional ties of two kinds. One of these, the tie with the leader, seems (at all events for these cases) to be more of a ruling factor than the other, which holds between the members of the group.

Now much else remains to be examined and described in the morphology of groups. We should have to start from the ascertained fact that a mere collection of people is not a group, so long as these ties have not been established in it; but we should have to admit that in any collection of people the tendency to form a psychological group may very easily come to the fore. We should have to give our attention to the different kinds of groups, more or less stable, that arise spontaneously, and to study the conditions of their origin and of their dissolution. We should above all be concerned with the distinction between groups which have a leader and leaderless groups. We should consider whether groups with leaders may not be the more primitive and complete, whether in the others an idea, an abstraction, may not take the place of the leader (a state of things to which religious groups, with their invisible head, form a transitional stage), and whether a common tendency, a wish in which a number of people can have a share, may not in the same way serve as a substitute. This abstraction, again, might be more or less completely embodied in the figure of what we might call a secondary leader, and interesting varieties would arise from the relation between the idea and the leader. The leader or the leading idea might also, so to speak, be negative; hatred against a particular person or institution might operate in just the same unifying way, and might call up the same kind of emotional ties as positive attachment. Then the question would also arise whether a leader is really indispensable to the essence of a groups - and other questions besides.

But all these questions, which may, moreover, have been dealt with in part in the literature of group psychology, will not succeed in diverting our interest from the fundamental psychological problems that confront us in the structure of a group. And our attention will first be attracted by a consideration which promises to bring us in the most direct way to a proof that libidinal ties are what characterize a group.

Let us keep before our eyes the nature of the emotional relations which hold between men in general. According to Schopenhauer's famous simile of the freezing porcupines no one can tolerate a too intimate approach to his neighbour.¹

The evidence of psycho-analysis shows that almost every intimate emotional relation between two people which lasts for some time - marriage, friendship, the relations between parents and children² - contains a sediment of feelings of aversion and hostility, which only escapes perception as a result of repression. This is less disguised in the common wrangles between business partners or in the grumbles of a subordinate at his superior. The same thing happens when men come together in larger units. Every time two families become connected by a marriage, each of them thinks itself superior to or of better birth than the other. Of two neighbouring towns each is the other's most jealous rival; every little canton looks down upon the others with contempt. Closely related races keep one another at arm's length; the South German cannot endure the North German, the Englishman casts every kind of aspersion upon the Scot, the Spaniard despises the Portuguese. We are no longer astonished that greater differences should lead to an almost insuperable repugnance, such as the Gallic people feel for the German, the Aryan for the Semite, and the white races for the coloured.

¹ 'A company of porcupines crowded themselves very close together one cold winter's day so as to profit by one another's warmth and so save themselves from being frozen to death. But soon they felt one another's quills, which induced them to separate again. And now, when the need for warmth brought them nearer together again, the second evil arose once more. So that they were driven backwards and forwards from one trouble to the other, until they had discovered a mean distance at which they could most tolerably exist.' (*Parerga und Paralipomena*, Part II, 31, 'Gleichnisse und Parabeln'.)

² Perhaps with the solitary exception of the relation of a mother to her son, which is based on narcissism, is not disturbed by subsequent rivalry, and is reinforced by a rudimentary attempt at sexual object-choice.

When this hostility is directed against people who are otherwise loved we describe it as ambivalence of feeling; and we explain the fact, in what is probably far too rational a manner, by means of the numerous occasions for conflicts of interest which arise precisely in such intimate relations. In the undisguised antipathies and aversions which people feel towards strangers with whom they have to do we may recognize the expression of self-love - of narcissism. This self-love works for the preservation of the individual, and behaves as though the occurrence of any divergence from his own particular lines of development involved a criticism of them and a demand for their alteration. We do not know why such sensitiveness should have been directed to just these details of differentiation; but it is unmistakable that in this whole connection men give evidence of a readiness for hatred, an aggressiveness, the source of which is unknown, and to which one is tempted to ascribe an elementary character.¹

But when a group is formed the whole of this intolerance vanishes, temporarily or permanently, within the group. So long as a group formation persists or so far as it extends, individuals in the group behave as though they were uniform, tolerate the peculiarities of its other members, equate themselves with them, and have no feeling of aversion towards them. Such a limitation of narcissism can, according to our theoretical views, only be produced by one factor, a libidinal tie with other people. Love for oneself knows only one barrier - love for others, love for objects.² The question will at once be raised whether community of interest in itself, without any addition of libido, must not necessarily lead to the toleration of other people and to considerateness for them. This objection may be met by the reply that nevertheless no lasting limitation of narcissism is effected in this way, since this tolerance does not persist longer than the immediate advantage gained from the other people's collaboration. But the practical importance of this discussion is less than might be supposed, for experience has shown that in cases of collaboration libidinal ties are regularly formed between the fellow-workers which prolong and solidify the relation between them to a point beyond what is merely profitable. The same thing occurs in men's social relations as has become familiar to psycho-analytic research in the course of the development of the individual libido. The libido attaches itself to the satisfaction of the great vital needs, and chooses as its first objects the people who have a share in that process. And in the development of mankind as a whole, just as in individuals, love alone acts as the civilizing factor in the sense that it brings a change from egoism to altruism. And this is true both of sexual love for women, with all the obligations which it involves of not harming the things that are dear to women, and also of desexualized, sublimated homosexual love for other men, which springs from work in common.

¹ In a recently published study, *Beyond the Pleasure Principle*, I have attempted to connect the polarity of love and hatred with a hypothetical opposition between instincts of life and death, and to establish the sexual instincts as the purest examples of the former, the instincts of life.

² See my paper on narcissism (1914c).

If therefore in groups narcissistic self-love is subject to limitations which do not operate outside them, that is cogent evidence that the essence of a group formation consists in new kinds of libidinal ties among the members of the group.

Our interest now leads us on to the pressing question as to what may be the nature of these ties which exist in groups. In the psycho-analytic study of neuroses we have hitherto been occupied almost exclusively with ties with objects made by love instincts which still pursue directly sexual aims. In groups there can evidently be no question of sexual aims of that kind. We are concerned here with love instincts which have been diverted from their original aims, though they do not operate with less energy on that account. Now, within the range of the usual sexual object-cathexis, we have already observed phenomena which represent a diversion of the instinct from its sexual aim. We have described them as degrees of being in love, and have recognized that they involve a certain encroachment upon the ego. We shall now turn our attention more closely to these phenomena of being in love, in the firm expectation of finding in them conditions which can be transferred to the ties that exist in groups. But we should also like to know whether this kind of object-cathexis, as we know it in sexual life, represents the only manner of emotional tie with other people, or whether we must take other mechanisms of the sort into account. As a matter of fact we learn from psycho-analysis that there do exist other mechanisms for emotional ties, the so-called *identifications*, insufficiently-known processes and hard to describe, the investigation of which will for some time keep us away from the subject of group psychology.

VII

IDENTIFICATION

Identification is known to psycho-analysis as the earliest expression of an emotional tie with another person. It plays a part in the early history of the Oedipus complex. A little boy will exhibit a special interest in his father; he would like to grow like him and be like him, and take his place everywhere. We may say simply that he takes his father as his ideal. This behaviour has nothing to do with a passive or feminine attitude towards his father (and towards males in general); it is on the contrary typically masculine. It fits in very well with the Oedipus complex, for which it helps to prepare the way.

At the same time as this identification with his father, or a little later, the boy has begun to develop a true object-cathexis towards his mother according to the attachment type. He then exhibits, therefore, two psychologically distinct ties: a straightforward sexual object-cathexis towards his mother and an identification with his father which takes him as his model. The two subsist side by side for a time without any mutual influence or interference. In consequence of the irresistible advance towards a unification of mental life, they come together at last; and the normal Oedipus complex originates from their confluence. The little boy notices that his father stands in his way with his mother. His identification with his father then takes on a hostile colouring and becomes identical with the wish to replace his father in regard to his mother as well. Identification, in fact, is ambivalent from the very first; it can turn into an expression of tenderness as easily as into a wish for someone's removal. It behaves like a derivative of the first, *oral* phase of the organization of the libido, in which the object that we long for and prize is assimilated by eating and is in that way annihilated as such. The cannibal, as we know, has remained at this standpoint; he has a devouring affection for his enemies and only devours people of whom he is fond.

The subsequent history of this identification with the father may easily be lost sight of. It may happen that the Oedipus complex becomes inverted, and that the father is taken as the object of a feminine attitude, an object from which the directly sexual instincts look for satisfaction; in that event the identification with the father has become the precursor of an object-tie with the father. The same holds good, with the necessary substitutions, of the baby daughter as well.

It is easy to state in a formula the distinction between an identification with the father and the choice of the father as an object. In the first case one's father is what one would like to *be* and in the second he is what one would like to *have*. The distinction, that is, depends upon whether the tie attaches to the subject or to the object of the ego. The former kind of tie is therefore already possible before any sexual object-choice has been made. It is much more difficult to give a clear metapsychological representation of the distinction. We can only see that identification endeavours to mould a person's own ego after the fashion of the one that has been taken as a model.

Let us disentangle identification as it occurs in the structure of a neurotic symptom from its rather complicated connections. Supposing that a little girl (and we will keep to her for the present) develops the same painful symptom as her mother - for instance, the same tormenting cough. This may come about in various ways. The identification may come from the Oedipus complex; in that case it signifies a hostile desire on the girl's part to take her mother's place, and the symptom expresses her object-love towards her father, and brings about a realization, under the influence of a sense of guilt, of her desire to take her mother's place: 'You wanted to be your mother, and now you *are* - anyhow so far as your sufferings are concerned.' This is the complete mechanism of the structure of a hysterical symptom. Or, on the other hand, the symptom may be the same as that of the person who is loved; so, for instance, Dora¹ imitated her father's cough. In that case we can only describe the state of things by saying *that identification has appeared instead of object-choice, and that object-choice has regressed to identification*. We have heard that identification is the earliest and original form of emotional tie; it often happens that under the conditions in which symptoms are constructed, that is, where there is repression and where the mechanisms of the unconscious are dominant, object-choice is turned back into identification - the ego assumes the characteristics of the object. It is noticeable that in these identifications the ego sometimes copies the person who is not loved and sometimes the one who is loved. It must also strike us that in both cases the identification is a partial and extremely limited one and only borrows a single trait from the person who is its object.

¹ In my 'Fragment of an Analysis of a Case of Hysteria' (1905e).

There is a third particularly frequent and important case of symptom formation, in which the identification leaves entirely out of account any object-relation to the person who is being copied. Supposing, for instance, that one of the girls in a boarding school has had a letter from someone with whom she is secretly in love which arouses her jealousy, and that she reacts to it with a fit of hysterics; then some of her friends who know about it will catch the fit, as we say, by mental infection. The mechanism is that of identification based upon the possibility or desire of putting oneself in the same situation. The other girls would like to have a secret love affair too, and under the influence of a sense of guilt they also accept the suffering involved in it. It would be wrong to suppose that they take on the symptom out of sympathy. On the contrary, the sympathy only arises out of the identification, and this is proved by the fact that infection or imitation of this kind takes place in circumstances where even less pre-existing sympathy is to be assumed than usually exists between friends in a girls' school. One ego has perceived a significant analogy with another upon one point - in our example upon openness to a similar emotion; an identification is thereupon constructed on this point, and, under the influence of the pathogenic situation, is displaced on to the symptom which the one ego has produced. The identification by means of the symptom has thus become the mark of a point of coincidence between the two egos which has to be kept repressed.

What we have learned from these three sources may be summarized as follows. First, identification is the original form of emotional tie with an object; secondly, in a regressive way it becomes a substitute for a libidinal object-tie, as it were by means of introjection of the object into the ego; and thirdly, it may arise with any new perception of a common quality shared with some other person who is not an object of the sexual instinct. The more important this common quality is, the more successful may this partial identification become, and it may thus represent the beginning of a new tie.

We already begin to divine that the mutual tie between members of a group is in the nature of an identification of this kind, based upon an important emotional common quality; and we may suspect that this common quality lies in the nature of the tie with the leader. Another suspicion may tell us that we are far from having exhausted the problem of identification, and that we are faced by the process which psychology calls 'empathy' and which plays the largest part in our understanding of what is inherently foreign to our ego in other people. But we shall here limit ourselves to the immediate emotional effects of identification, and shall leave on one side its significance for our intellectual life.

Psycho-analytic research, which has already occasionally attacked the more difficult problems of the psychoses, has also been able to exhibit identification to us in some other cases which are not immediately comprehensible. I shall treat two of these cases in detail as material for our further consideration.

The genesis of male homosexuality in a large class of cases is as follows. A young man has been unusually long and intensely fixated upon his mother in the sense of the Oedipus complex. But at last, after the end of puberty, the time comes for exchanging his mother for some other sexual object. Things take a sudden turn: the young man does not abandon his mother, but identifies himself with her; he transforms himself into her, and now looks about for objects which can replace his ego for him, and on which he can bestow such love and care as he has experienced from his mother. This is a frequent process, which can be confirmed as often as one likes, and which is naturally quite independent of any hypothesis that may be made as to the organic driving force and the motives of the sudden transformation. A striking thing about this identification is its ample scale; it remoulds the ego in one of its important features - in its sexual character - upon the model of what has hitherto been the object. In this process the object itself is renounced - whether entirely or in the sense of being preserved only in the unconscious is a question outside the present discussion. Identification with an object that is renounced or lost, as a substitute for that object - introjection of it into the ego - is indeed no longer a novelty to us. A process of the kind may sometimes be directly observed in small children. A short time ago an observation of this sort was published in the *Internationale Zeitschrift für Psychoanalyse*. A child who was unhappy over the loss of a kitten declared straight out that now he himself was the kitten, and accordingly crawled about on all fours, would not eat at table, etc.¹

¹ Marcuszewicz (1920).

Another such instance of introjection of the object has been provided by the analysis of melancholia, an affection which counts among the most notable of its exciting causes the real or emotional loss of a loved object. A leading characteristic of these cases is a cruel self-depreciation of the ego combined with relentless self-criticism and bitter self-reproaches. Analyses have shown that this disparagement and these reproaches apply at bottom to the object and represent the ego's revenge upon it. The shadow of the object has fallen upon the ego, as I have said elsewhere.¹ The introjection of the object is here unmistakably clear.

But these melancholias also show us something else, which may be of importance for our later discussions. They show us the ego divided, fallen apart into two pieces, one of which rages against the second. This second piece is the one which has been altered by introjection and which contains the lost object. But the piece which behaves so cruelly is not unknown to us either. It comprises the conscience, a critical agency within the ego, which even in normal times takes up a critical attitude towards the ego, though never so relentlessly and so unjustifiably. On previous occasions² we have been driven to the hypothesis that some such agency develops in our ego which may cut itself off from the rest of the ego and come into conflict with it. We have called it the 'ego ideal', and by way of functions we have ascribed to it self-observation, the moral conscience, the censorship of dreams, and the chief influence in repression. We have said that it is the heir to the original narcissism in which the childish ego enjoyed self-sufficiency; it gradually gathers up from the influences of the environment the demands which that environment makes upon the ego and which the ego cannot always rise to; so that a man, when he cannot be satisfied with his ego itself, may nevertheless be able to find satisfaction in the ego ideal which has been differentiated out of the ego. In delusions of observation, as we have further shown, the disintegration of this agency has become patent, and has thus revealed its origin in the influence of superior powers, and above all of parents.³ But we have not forgotten to add that the amount of distance between this ego ideal and the real ego is very variable from one individual to another, and that with many people this differentiation within the ego does not go further than with children.

¹ See 'Mourning and Melancholia' (1917e).

² In my paper on narcissism (1914c).

³ Section III of my paper on narcissism.

But before we can employ this material for understanding the libidinal organization of groups, we must take into account some other examples of the mutual relations between the object and the ego.¹

¹ We are very well aware that we have not exhausted the nature of identification with these examples taken from pathology, and that we have consequently left part of the riddle of group formations untouched. A far more fundamental and comprehensive psychological analysis would have to intervene at this point. A path leads from identification by way of imitation to empathy, that is, to the comprehension of the mechanism by means of which we are enabled to take up any attitude at all towards another mental life. Moreover there is still much to be explained in the manifestations of existing identifications. These result among other things in a person limiting his aggressiveness towards those with whom he has identified himself, and in his sparing them and giving them help. The study of such identifications, like those, for instance which lie at the root of clan feeling, led Robertson Smith (*Kinship and Marriage*, 1885) to the surprising discovery that they rest upon the acknowledgement of the possession of a common substance, and may even therefore be created by a meal eaten in common. This feature makes it possible to connect this kind of identification with the early history of the human family which I constructed in *Totem and Taboo*.

VIII

BEING IN LOVE AND HYPNOSIS

Even in its caprices the usage of language remains true to some kind of reality. Thus it gives the name of 'love' to a great many kinds of emotional relationship which we too group together theoretically as love; but then again it feels a doubt whether this love is real, true, actual love, and so hints at a whole scale of possibilities within the range of the phenomena of love. We shall have no difficulty in making the same discovery from our own observations.

In one class of cases being in love is nothing more than object cathexis on the part of the sexual instincts with a view to directly sexual satisfaction, a cathexis which expires, moreover, when this aim has been reached; this is what is called common, sensual love. But, as we know, the libidinal situation rarely remains so simple. It was possible to calculate with certainty upon the revival of the need which had just expired; and this must no doubt have been the first motive for directing a lasting cathexis upon the sexual object and for 'loving' it in the passionless intervals as well.

To this must be added another factor derived from the very remarkable course of development which is pursued by the erotic life of man. In its first phase, which has usually come to an end by the time a child is five years old, he has found the first object for his love in one or other of his parents, and all of his sexual instincts with their demand for satisfaction have been united upon this object. The repression which then sets in compels him to renounce the greater number of these infantile sexual aims, and leaves behind a profound modification in his relation to his parents. The child still remains tied to his parents, but by instincts which must be described as being 'inhibited in their aim'. The emotions which he feels henceforward towards these objects of his love are characterized as 'affectionate'. It is well known that the earlier 'sensual' tendencies remain more or less strongly preserved in the unconscious, so that in a certain sense the whole of the original current continues to exist.¹

¹ See my *Three Essays* (1905d).

At puberty, as we know, there set in new and very strong impulsions towards directly sexual aims. In unfavourable cases they remain separate, in the form of a sensual current, from the 'affectionate' trends of feeling which persist. We then have before us a picture whose two aspects are typified with such delight by certain schools of literature. A man will show a sentimental enthusiasm for women whom he deeply respects but who do not excite him to sexual activities, and he will only be potent with other women whom he does not 'love' and thinks little of or even despises.¹ More often, however, the adolescent succeeds in bringing about a certain degree of synthesis between the unsensual, heavenly love and the sensual, earthly love, and his relation to his sexual object is characterized by the interaction of uninhibited instincts and of instincts inhibited in their aim. The depth to which anyone is in love, as contrasted with his purely sensual desire, may be measured by the size of the share taken by the aim-inhibited instincts of affection.

In connection with this question of being in love we have always been struck by the phenomenon of sexual overvaluation - the fact that the loved object enjoys a certain amount of freedom from criticism, and that all its characteristics are valued more highly than those of people who are not loved, or than its own were at a time when it itself was not loved. If the sensual impulsions are more or less effectively repressed or set aside, the illusion is produced that the object has come to be sensually loved on account of its spiritual merits, whereas on the contrary these merits may really only have been lent to it by its sensual charm.

The tendency which falsifies judgement in this respect is that of *idealization*. But now it is easier for us to find our bearings. We see that the object is being treated in the same way as our own ego, so that when we are in love a considerable amount of narcissistic libido overflows on to the object. It is even obvious, in many forms of love-choice, that the object serves as a substitute for some unattained ego ideal of our own. We love it on account of the perfections which we have striven to reach for our own ego, and which we should now like to procure in this roundabout way as a means of satisfying our narcissism.

¹ 'On the Universal Tendency to Debasement in the Sphere of Love' (1912*d*).

If the sexual overvaluation and the being in love increase even further, then the interpretation of the picture becomes still more unmistakable. The impulsions whose trend is towards directly sexual satisfaction may now be pushed into the background entirely, as regularly happens, for instance, with a young man's sentimental passion; the ego becomes more and more unassuming and modest, and the object more and more sublime and precious, until at last it gets possession of the entire self-love of the ego, whose self-sacrifice thus follows as a natural consequence. The object has, so to speak, consumed the ego. Traits of humility, of the limitation of narcissism, and of self-injury occur in every case of being in love; in the extreme case they are merely intensified, and as a result of the withdrawal of the sensual claims they remain in solitary supremacy.

This happens especially easily with love that is unhappy and cannot be satisfied; for in spite of everything each sexual satisfaction always involves a reduction in sexual overvaluation. Contemporaneously with this 'devotion' of the ego to the object, which is no longer to be distinguished from a sublimated devotion to an abstract idea, the functions allotted to the ego ideal entirely cease to operate. The criticism exercised by that agency is silent; everything that the object does and asks for is right and blameless. Conscience has no application to anything that is done for the sake of the object; in the blindness of love remorselessness is carried to the pitch of crime. The whole situation can be completely summarized in a formula: *The object has been put in the place of the ego ideal.*

It is now easy to define the difference between identification and such extreme developments of being in love as may be described as 'fascination' or 'bondage'. In the former case the ego has enriched itself with the properties of the object, it has 'introjected' the object into itself, as Ferenczi expresses it. In the second case it is impoverished, it has surrendered itself to the object, it has substituted the object for its own most important constituent. Closer consideration soon makes it plain, however, that this kind of account creates an illusion of contradistinctions that have no real existence. Economically there is no question of impoverishment or enrichment; it is even possible to describe an extreme case of being in love as a state in which the ego has introjected the object into itself. Another distinction is perhaps better calculated to meet the essence of the matter. In the case of identification the object has been lost or given up; it is then set up again inside the ego, and the ego makes a partial alteration in itself after the model of the lost object. In the other case the object is retained, and there is a hypercathexis of it by the ego and at the ego's expense. But here again a difficulty presents itself. Is it quite certain that identification presupposes that object-cathexis has been given up? Can there be no identification while the object is retained? And before we embark upon a discussion of this delicate question, the perception may already be beginning to dawn on us that yet another alternative embraces the real essence of the matter, namely, *whether the object is put in the place of the ego or of the ego ideal.*

From being in love to hypnosis is evidently only a short step. The respects in which the two agree are obvious. There is the same humble subjection, the same compliance, the same absence of criticism, towards the hypnotist as towards the loved object. There is the same sapping of the subject's own initiative; no one can doubt that the hypnotist has stepped into the place of the ego ideal. It is only that everything is even clearer and more intense in hypnosis, so that it would be more to the point to explain being in love by means of hypnosis than the other way round. The hypnotist is the sole object, and no attention is paid to any but him. The fact that the ego experiences in a dreamlike way whatever he may request or assert reminds us that we omitted to mention among the functions of the ego ideal the business of testing the reality of things.¹ No wonder that the ego takes a perception for real if its reality is vouched for by the mental agency which ordinarily discharges the duty of testing the reality of things. The complete absence of impulsions which are uninhibited in their sexual aims contributes further towards the extreme purity of the phenomena. The hypnotic relation is the unlimited devotion of someone in love, but with sexual satisfaction excluded; whereas in the actual case of being in love this kind of satisfaction is only temporarily kept back, and remains in the background as a possible aim at some later time.

¹ Cf. Freud (1917*d*). - There seems, however, to be some doubt whether the attribution of this function to the ego ideal is justified. The point requires thorough discussion.

But on the other hand we may also say that the hypnotic relation is (if the expression is permissible) a group formation with two members. Hypnosis is not a good object for comparison with a group formation, because it is truer to say that it is identical with it. Out of the complicated fabric of the group it isolates one element for us - the behaviour of the individual to the leader. Hypnosis is distinguished from a group formation by this limitation of number, just as it is distinguished from being in love by the absence of directly sexual trends. In this respect it occupies a middle position between the two.

It is interesting to see that it is precisely those sexual impulsions that are inhibited in their aims which achieve such lasting ties between people. But this can easily be understood from the fact that they are not capable of complete satisfaction, while sexual impulsions which are uninhibited in their aims suffer an extraordinary reduction through the discharge of energy every time the sexual aim is attained. It is the fate of sensual love to become extinguished when it is satisfied; for it to be able to last, it must from the beginning be mixed with purely affectionate components - with such, that is, as are inhibited in their aims - or it must itself undergo a transformation of this kind.

Hypnosis would solve the riddle of the libidinal constitution of groups for us straight away, if it were not that it itself exhibits some features which are not met by the rational explanation we have hitherto given of it as a state of being in love with the directly sexual trends excluded. There is still a great deal in it which we must recognize as unexplained and mysterious. It contains an additional element of paralysis derived from the relation between someone with superior power and someone who is without power and helpless - which may afford a transition to the hypnosis of fright which occurs in animals. The manner in which it is produced and its relationship to sleep are not clear; and the puzzling way in which some people are subject to it, while others resist it completely, points to some factor still unknown which is realized in it and which perhaps alone makes possible the purity of the attitudes of the libido which it exhibits. It is noticeable that, even when there is complete suggestive compliance in other respects, the moral conscience of the person hypnotized may show resistance. But this may be due to the fact that in hypnosis as it is usually practised some knowledge may be retained that what is happening is only a game, an untrue reproduction of another situation of far more importance to life.

But after the preceding discussions we are quite in a position to give the formula for the libidinal constitution of groups, or at least of such groups as we have hitherto considered - namely, those that have a leader and have not been able by means of too much 'organization' to acquire secondarily the characteristics of an individual. *A primary group of this kind is a number of individuals who have put one and the same object in the place of their ego ideal and have consequently identified themselves with one another in their ego.* This condition admits of graphic representation:

IX

THE HERD INSTINCT

We cannot for long enjoy the illusion that we have solved the riddle of the group with this formula. It is impossible to escape the immediate and disturbing recollection that all we have really done has been to shift the question on to the riddle of hypnosis, about which so many points have yet to be cleared up. And now another objection shows us our further path.

It might be said that the intense emotional ties which we observe in groups are quite sufficient to explain one of their characteristics - the lack of independence and initiative in their members, the similarity in the reactions of all of them, their reduction, so to speak, to the level of group individuals. But if we look at it as a whole, a group shows us more than this. Some of its features - the weakness of intellectual ability, the lack of emotional restraint, the incapacity for moderation and delay, the inclination to exceed every limit in the expression of emotion and to work it off completely in the form of action - these and similar features, which we find so impressively described in Le Bon, show an unmistakable picture of a regression of mental activity to an earlier stage such as we are not surprised to find among savages or children. A regression of this sort is in particular an essential characteristic of common groups, while, as we have heard, in organized and artificial groups it can to a large extent be checked.

We thus have an impression of a state in which an individual's private emotional impulses and intellectual acts are too weak to come to anything by themselves and are entirely dependent for this on being reinforced by being repeated in a similar way in the other members of the group. We are reminded of how many of these phenomena of dependence are part of the normal constitution of human society, of how little originality and personal courage are to be found in it, of how much every individual is ruled by those attitudes of the group mind which exhibit themselves in such forms as racial characteristics, class prejudices, public opinion, etc. The influence of suggestion becomes a greater riddle for us when we admit that it is not exercised only by the leader, but by every individual upon every other individual; and we must reproach ourselves with having unfairly emphasized the relation to the leader and with having kept the other factor of mutual suggestion too much in the background.

After this encouragement to modesty, we shall be inclined to listen to another voice, which promises us an explanation based upon simpler grounds. Such a one is to be found in Trotter's thoughtful book on the herd instinct (1916), concerning which my only regret is that it does not entirely escape the antipathies that were set loose by the recent great war.

Trotter derives the mental phenomena that are described as occurring in groups from a herd instinct ('gregariousness'), which is innate in human beings just as in other species of animals. Biologically, he says, this gregariousness is an analogy to multicellularity and as it were a continuation of it. (In terms of the libido theory it is a further manifestation of the tendency which proceeds from the libido and which is felt by all living beings of the same kind, to combine in more and more comprehensive units.¹) The individual feels incomplete if he is alone. The fear shown by small children would seem already to be an expression of this herd instinct. Opposition to the herd is as good as separation from it, and is therefore anxiously avoided. But the herd turns away from anything that is new or unusual. The herd instinct would appear to be something primary, something which cannot be split up.

Trotter gives as the list of instincts which he considers as primary those of self-preservation, of nutrition, of sex, and of the herd. The last often comes into opposition with the others. The feelings of guilt and of duty are the peculiar possessions of a gregarious animal. Trotter also derives from the herd instinct the repressive forces which psycho-analysis has shown to exist in the ego, and from the same source accordingly the resistances which the physician comes up against in psycho-analytic treatment. Speech owes its importance to its aptitude for mutual understanding in the herd, and upon it the identification of the individuals with one another largely rests.

¹ See *Beyond the Pleasure Principle*.

While Le Bon is principally concerned with typical transient group formations, and McDougall with stable associations, Trotter has chosen as the centre of his interest the most generalized form of assemblage in which man, that *ξῶον πολιτιστον*, passes his life, and he gives us its psychological basis. But Trotter is under no necessity of tracing back the herd instinct, for he characterizes it as primary and not further reducible. Boris Sidis's attempt, to which he refers, at tracing the herd instinct back to suggestibility is fortunately superfluous as far as he is concerned; it is an explanation of a familiar and unsatisfactory type, and the converse proposition - that suggestibility is a derivative of the herd instinct - would seem to me to throw far more light on the subject.

But Trotter's exposition is open, with even more justice than the others, to the objection that it takes too little account of the leader's part in a group, while we incline rather to the opposite judgement, that it is impossible to grasp the nature of a group if the leader is disregarded. The herd instinct leaves no room at all for the leader; he is merely thrown in along with the herd, almost by chance; it follows, too, that no path leads from this instinct to the need for a God; the herd is without a herdsman. But besides this, Trotter's exposition can be undermined psychologically; that is to say, it can be made at all events probable that the herd instinct is not irreducible, that it is not primary in the same sense as the instinct of self-preservation and the sexual instinct.

It is naturally no easy matter to trace the ontogenesis of the herd instinct. The fear which is shown by small children when they are left alone, and which Trotter claims as being already a manifestation of the instinct, nevertheless suggests more readily another interpretation. The fear relates to the child's mother, and later to other familiar people, and it is the expression of an unfulfilled desire, which the child does not yet know how to deal with in any way except by turning it into anxiety.¹ Nor is the child's fear when it is alone pacified by the sight of any haphazard 'member of the herd', but on the contrary it is brought into existence by the approach of a 'stranger' of this sort. Then for a long time nothing in the nature of herd instinct or group feeling is to be observed in children. Something like it first grows up, in a nursery containing many children, out of the children's relation to their parents, and it does so as a reaction to the initial envy with which the elder child receives the younger one. The elder child would certainly like to put his successor jealously aside, to keep it away from the parents, and to rob it of all its privileges; but in the face of the fact that this younger child (like all that come later) is loved by the parents as much as he himself is, and in consequence of the impossibility of his maintaining his hostile attitude without damaging himself, he is forced into identifying himself with the other children. So there grows up in the troop of children a communal or group feeling, which is then further developed at school. The first demand made by this reaction-formation is for justice, for equal treatment for all. We all know how loudly and implacably this claim is put forward at school. If one cannot be the favourite oneself, at all events nobody else shall be the favourite. This transformation - the replacing of jealousy by a group feeling in the nursery and classroom - might be considered improbable, if the same process could not later on be observed again in other circumstances. We have only to think of the troop of women and girls, all of them in love in an enthusiastically sentimental way, who crowd round a singer or pianist after his performance. It would certainly be easy for each of them to be jealous of the rest; but, in the face of their numbers and the consequent impossibility of their reaching the aim of their love, they renounce it, and, instead of pulling out one another's hair, they act as a united group, do homage to the hero of the occasion with their common actions, and would probably be glad to have a share of *his* flowing locks. Originally rivals, they have succeeded in identifying themselves with one another by means of a similar love for the same object. When, as is usual, an instinctual situation is capable of various outcomes, we shall not be surprised that the actual outcome is one which brings with it the possibility of a certain amount of satisfaction, whereas some other outcome, in itself more obvious, is passed over because the circumstances of life prevent its leading to any such satisfaction.

¹ See the remarks upon anxiety in my *Introductory Lectures* (1916-17), Lecture XXV.

What appears later on in society in the shape of *Gemeingeist*, *esprit de corps*, 'group spirit', etc., does not belie its derivation from what was originally envy. No one must want to put himself forward, every one must be the same and have the same. Social justice means that we deny ourselves many things so that others may have to do without them as well, or, what is the same thing, may not be able to ask for them. This demand for equality is the root of social conscience and the sense of duty. It reveals itself unexpectedly in the syphilitic's dread of infecting other people, which psycho-analysis has taught us to understand. The dread exhibited by these poor wretches corresponds to their violent struggles against the unconscious wish to spread their infection on to other people; for why should they alone be infected and cut off from so much? why not other people as well? And the same germ is to be found in the apt story of the judgement of Solomon. If one woman's child is dead, the other shall not have a live one either. The bereaved woman is recognized by this wish.

Thus social feeling is based upon the reversal of what was first a hostile feeling into a positively-toned tie in the nature of an identification. So far as we have hitherto been able to follow the course of events, this reversal seems to occur under the influence of a common affectionate tie with a person outside the group. We do not ourselves regard our analysis of identification as exhaustive, but it is enough for our present purpose that we should revert to this one feature - its demand that equalization shall be consistently carried through. We have already heard in the discussion of the two artificial groups, Church and army, that their necessary precondition is that all their members should be loved in the same way by one person, the leader. Do not let us forget, however, that the demand for equality in a group applies only to its members and not to the leader. All the members must be equal to one another, but they all want to be ruled by one person. Many equals, who can identify themselves with one another, and a single person superior to them all - that is the situation that we find realized in groups which are capable of subsisting. Let us venture, then, to correct Trotter's pronouncement that man is a herd animal and assert that he is rather a horde animal, an individual creature in a horde led by a chief.

X

THE GROUP AND THE PRIMAL HORDE

In 1912 I took up a conjecture of Darwin's to the effect that the primitive form of human society was that of a horde ruled over despotically by a powerful male. I attempted to show that the fortunes of this horde have left indestructible traces upon the history of human descent; and, especially, that the development of totemism, which comprises in itself the beginnings of religion, morality, and social organization, is connected with the killing of the chief by violence and the transformation of the paternal horde into a community of brothers.¹ To be sure, this is only a hypothesis, like so many others with which archaeologists endeavour to lighten the darkness of prehistoric times - a 'Just-So Story', as it was amusingly called by a not unkind English critic; but I think it is creditable to such a hypothesis if it proves able to bring coherence and understanding into more and more new regions.

Human groups exhibit once again the familiar picture of an individual of superior strength among a troop of equal companions, a picture which is also contained in our idea of the primal horde. The psychology of such a group, as we know it from the descriptions to which we have so often referred - the dwindling of the conscious individual personality, the focusing of thoughts and feelings into a common direction, the predominance of the affective side of the mind and of unconscious psychical life, the tendency to the immediate carrying out of intentions as they emerge - all this corresponds to a state of regression to a primitive mental activity, of just such a sort as we should be inclined to ascribe to the primal horde.²

¹ *Totem and Taboo* (1912-13)

² What we have just described in our general characterization of mankind must apply especially to the primal horde. The will of the individual was too weak; he did not venture upon action. No impulses whatever came into existence except collective ones; there was only a common will, there were no single ones. An idea did not dare to turn itself into an act of will unless it felt itself reinforced by a perception of its general diffusion. This weakness of the idea is to be explained by the strength of the emotional tie which is shared by all the members of the horde; but the similarity in the circumstances of their life and the absence of any private property assist in determining the uniformity of their individual mental acts. As we may observe with children and soldiers, common activity is not excluded even in the excretory functions. The one great exception is provided by the sexual act, in which a third person is at best superfluous and in the extreme case is condemned to a state of painful expectancy. As to the reaction of the sexual need (for genital satisfaction) towards gregariousness, see below.

Thus the group appears to us as a revival of the primal horde. Just as primitive man survives potentially in every individual, so the primal horde may arise once more out of any random collection; in so far men are habitually under the sway of group formation we recognize in it the survival of the primal horde. We must conclude that the psychology of groups is the oldest human psychology; what we have isolated as individual psychology, by neglecting all traces of the group, has only since come into prominence out of the old group psychology, by a gradual process which may still, perhaps, be described as incomplete. We shall later venture upon an attempt at specifying the point of departure of this development.

Further reflection will show us in what respect this statement requires correction. Individual psychology must, on the contrary, be just as old as group psychology, for from the first there were two kinds of psychologies, that of the individual members of the group and that of the father, chief, or leader. The members of the group were subject to ties just as we see them to-day, but the father of the primal horde was free. His intellectual acts were strong and independent even in isolation, and his will needed no reinforcement from others. Consistency leads us to assume that his ego had few libidinal ties; he loved no one but himself, or other people only in so far as they served his needs. To objects his ego gave away no more than was barely necessary.

He, at the very beginning of the history of mankind, was the 'superman' whom Nietzsche only expected from the future. Even to-day the members of a group stand in need of the illusion that they are equally and justly loved by their leader; but the leader himself need love no one else, he may be of a masterful nature, absolutely narcissistic, self-confident and independent. We know that love puts a check upon narcissism, and it would be possible to show how, by operating in this way, it became a factor of civilization.

The primal father of the horde was not yet immortal, as he later became by deification. If he died, he had to be replaced; his place was probably taken by a youngest son, who had up to then been a member of the group like any other. There must therefore be a possibility of transforming group psychology into individual psychology; a condition must be discovered under which such a transformation is easily accomplished, just as it is possible for bees in case of necessity to turn a larva into a queen instead of into a worker. One can imagine only one possibility: the primal father had prevented his sons from satisfying their directly sexual impulses; he forced them into abstinence and consequently into the emotional ties with him and with one another which could arise out of those of their impulses that were inhibited in their sexual aim. He forced them, so to speak, into group psychology. His sexual jealousy and intolerance became in the last resort the causes of group psychology.¹

Whoever became his successor was also given the possibility of sexual satisfaction, and was by that means offered a way out of the conditions of group psychology. The fixation of the libido to woman and the possibility of satisfaction without any need for delay or accumulation made an end of the importance of those of his sexual impulses that were inhibited in their aim, and allowed his narcissism always to rise to its full height. We shall return in a postscript to this connection between love and character formation.

We may further emphasize, as being specially instructive, the relation that holds between the contrivance by means of which an artificial group is held together and the constitution of the primal horde. We have seen that with an army and a Church this contrivance is the illusion that the leader loves all of the individuals equally and justly. But this is simply an idealistic remodelling of the state of affairs in the primal horde, where all of the sons knew that they were equally *persecuted* by the primal father, and *feared* him equally. This same recasting upon which all social duties are built up is already presupposed by the next form of human society, the totemic clan. The indestructible strength of the family as a natural group formation rests upon the fact that this necessary presupposition of the father's equal love can have a real application in the family.

¹ It may perhaps also be assumed that the sons, when they were driven out and separated from their father, advanced from identification with one another to homosexual object-love, and in this way won freedom to kill their father.

But we expect even more of this derivation of the group from the primal horde. It ought also to help us to understand what is still incomprehensible and mysterious in group formations - all that lies hidden behind the enigmatic words 'hypnosis' and 'suggestion'. And I think it can succeed in this too. Let us recall that hypnosis has something positively uncanny about it; but the characteristic of uncanniness suggests something old and familiar that has undergone repression.¹ Let us consider how hypnosis is induced. The hypnotist asserts that he is in possession of a mysterious power that robs the subject of his own will; or, which is the same thing, the subject believe it of him. This mysterious power (which is even now often described popularly as 'animal magnetism') must be the same power that is looked upon by primitive people as the source of taboo, the same that emanates from kings and chieftains and makes it dangerous to approach them (*mana*). The hypnotist, then, is supposed to be in possession of this power; and how does he manifest it? By telling the subject to look him in the eyes; his most typical method of hypnotizing is by his look. But it is precisely the *sight* of the chieftain that is dangerous and unbearable for primitive people, just as later that of the Godhead is for mortals. Even Moses had to act as an intermediary between his people and Jehovah, since the people could not support the sight of God; and when he returned from the presence of God his face shone - some of the *mana* had been transferred on to him, just as happens with the intermediary among primitive people.²

¹ Cf. 'The "Uncanny"' (1919*h*).

² See *Totem and Taboo* and the sources there quoted.

It is true that hypnosis can also be evoked in other ways, for instance by fixing the eyes upon a bright object or by listening to a monotonous sound. This is misleading and has given occasion to inadequate physiological theories. In point of fact these procedures merely serve to divert conscious attention and to hold it riveted. The situation is the same as if the hypnotist had said to the subject: 'Now concern yourself exclusively with my person; the rest of the world is quite uninteresting.' It would of course be technically inexpedient for a hypnotist to make such a speech; it would tear the subject away from his unconscious attitude and stimulate him to conscious opposition. The hypnotist avoids directing the subject's conscious thoughts towards his own intentions, and makes the person upon whom he is experimenting sink into an activity in which the world is bound to seem uninteresting to him; but at the same time the subject is in reality unconsciously concentrating his whole attention upon the hypnotist, and is getting into an attitude of *rappor*t, of transference on to him. Thus the indirect methods of hypnotizing, like many of the technical procedures used in making jokes, have the effect of checking certain distributions of mental energy which would interfere with the course of events in the unconscious, and they lead eventually to the same result as the direct methods of influence by means of staring or stroking.¹

¹ This situation, in which the subject's attitude is unconsciously directed towards the hypnotist, while he is consciously occupied with monotonous and uninteresting perceptions, finds a parallel among the events of psycho-analytic treatment, which deserves to be mentioned here. At least once in the course of every analysis a moment comes when the patient obstinately maintains that just now positively nothing whatever occurs to his mind. His free associations come to a stop and the usual incentives for putting them in motion fail in their effect. If the analyst insists, the patient is at last induced to admit that he is thinking of the view from the consulting-room window, of the wall-paper that he sees before him, or of the gas-lamp hanging from the ceiling. Then one knows at once that he has gone off into the transference and that he is engaged upon what are still unconscious thoughts relating to the physician; and one sees the stoppage in the patient's associations disappear, as soon as he has been given this explanation.

Ferenczi has made the true discovery that when a hypnotist gives the command to sleep, which is often done at the beginning of hypnosis, he is putting himself in the place of the subject's parents. He thinks that two sorts of hypnotism are to be distinguished: one coaxing and soothing, which he considers is modelled on the mother, and another threatening, which is derived from the father. Now the command to sleep in hypnosis means nothing more nor less than an order to withdraw all interest from the world and to concentrate it on the person of the hypnotist. And it is so understood by the subject; for in this withdrawal of interest from the external world lies the psychological characteristic of sleep, and the kinship between sleep and the state of hypnosis is based on it.

By the measures that he takes, then, the hypnotist awakens in the subject a portion of his archaic heritage which had also made him compliant towards his parents and which had experienced an individual re-animation in his relation to his father; what is thus awakened is the idea of a paramount and dangerous personality, towards whom only a passive-masochistic attitude is possible, to whom one's will has to be surrendered, - while to be alone with him, 'to look him in the face', appears a hazardous enterprise. It is only in some such way as this that we can picture the relation of the individual member of the primal horde to the primal father. As we know from other reactions, individuals have preserved a variable degree of personal aptitude for reviving old situations of this kind. Some knowledge that in spite of everything hypnosis is only a game, a deceptive renewal of these old impressions, may, however, remain behind and take care that there is a resistance against any too serious consequences of the suspension of the will in hypnosis.

The uncanny and coercive characteristics of group formations, which are shown in the phenomena of suggestion that accompany them, may therefore with justice be traced back to the fact of their origin from the primal horde. The leader of the group is still the dreaded primal father; the group still wishes to be governed by unrestricted force; it has an extreme passion for authority; in Le Bon's phrase, it has a thirst for obedience. The primal father is the group ideal, which governs the ego in the place of the ego ideal. Hypnosis has a good claim to being described as a group of two. There remains as a definition for suggestion: a conviction which is not based upon perception and reasoning but upon an erotic tie.¹

¹ It seems to me worth emphasizing the fact that the discussions in this section have induced us to give up Bernheim's conception of hypnosis and go back to the *naïf* earlier one. According to Bernheim all hypnotic phenomena are to be traced to the factor of suggestion, which is not itself capable of further explanation. We have come to the conclusion that suggestion is a partial manifestation of the state of hypnosis, and that hypnosis is solidly founded upon a predisposition which has survived in the unconscious from the early history of the human family.

XI

A DIFFERENTIATING GRADE IN THE EGO

If we survey the life of an individual man of to-day, bearing in mind the mutually complementary accounts of group psychology given by the authorities, we may lose the courage, in face of the complications that are revealed, to attempt a comprehensive exposition. Each individual is a component part of numerous groups, he is bound by ties of identification in many directions, and he has built up his ego ideal upon the most various models. Each individual therefore has a share in numerous group minds - those of his race, of his class, of his creed, of his nationality, etc. - and he can also raise himself above them to the extent of having a scrap of independence and originality. Such stable and lasting group formations, with their uniform and constant effects, are less striking to an observer than the rapidly formed and transient groups from which Le Bon has made his brilliant psychological character sketch of the group mind. And it is just in these noisy ephemeral groups, which are as it were superimposed upon the others, that we are met by the prodigy of the complete, even though only temporary, disappearance of exactly what we have recognized as individual acquirements.

We have interpreted this prodigy as meaning that the individual gives up his ego ideal and substitutes for it the group ideal as embodied in the leader. And we must add by way of correction that the prodigy is not equally great in every case. In many individuals the separation between the ego and the ego ideal is not very far advanced; the two still coincide readily; the ego has often preserved its earlier narcissistic self-complacency. The selection of the leader is very much facilitated by this circumstance. He need often only possess the typical qualities of the individuals concerned in a particularly clearly marked and pure form, and need only give an impression of greater force and of more freedom of libido; and in that case the need for a strong chief will often meet him half-way and invest him with a predominance to which he would otherwise perhaps have had no claim. The other members of the group, whose ego ideal would not, apart from this, have become embodied in his person without some correction, are then carried away with the rest by 'suggestion', that is to say, by means of identification.

We are aware that what we have been able to contribute towards the explanation of the libidinal structure of groups leads back to the distinction between the ego and the ego ideal and to the double kind of tie which this makes possible - identification, and putting the object in the place of the ego ideal. The assumption of this kind of differentiating grade in the ego as a first step in an analysis of the ego must gradually establish its justification in the most various regions of psychology. In my paper on narcissism I have put together all the pathological material that could at the moment be used in support of this differentiation. But it may be expected that when we penetrate deeper into the psychology of the psychoses its significance will be discovered to be far greater. Let us reflect that the ego now enters into the relation of an object to the ego ideal which has been developed out of it, and that all the interplay between an external object and the ego as a whole, with which our study of the neuroses has made us acquainted, may possibly be repeated upon this new scene of action within the ego.

In this place I shall only follow up one of the consequences which seem possible from this point of view, thus resuming the discussion of a problem which I was obliged to leave unsolved elsewhere.¹ Each of the mental differentiations that we have become acquainted with represents a fresh aggravation of the difficulties of mental functioning, increases its instability, and may become the starting-point for its breakdown, that is, for the onset of a disease. Thus, by being born we have made the step from an absolutely self-sufficient narcissism to the perception of a changing external world and the beginnings of the discovery of objects. And with this is associated the fact that we cannot endure the new state of things for long, that we periodically revert from it, in our sleep, to our former condition of absence of stimulation and avoidance of objects. It is true, however, that in this we are following a hint from the external world, which, by means of the periodical change of day and night, temporarily withdraws the greater part of the stimuli that affect us. The second example of such a step, pathologically more important, is subject to no such qualification. In the course of development we have effected a separation of our mental existence into a coherent ego and into an unconscious and repressed portion which is left outside it; and we know that the stability of this new acquisition is exposed to constant shocks. In dreams and in neuroses what is thus excluded knocks for admission at the gates, guarded though they are by resistances; and in our waking health we make use of special artifices for allowing what is repressed to circumvent the resistances and for receiving it temporarily into our ego to the increase of our pleasure. Jokes and humour, and to some extent the comic in general, may be regarded in this light. Everyone acquainted with the psychology of the neuroses will think of similar examples of less importance; but I hasten on to the application I have in view.

¹ 'Mourning and Melancholia' (1917e).

It is quite conceivable that the separation of the ego ideal from the ego cannot be borne for long either, and has to be temporarily undone. In all renunciations and limitations imposed upon the ego a periodical infringement of the prohibition is the rule; this indeed is shown by the institution of festivals, which in origin are nothing less nor more than excesses provided by law and which owe their cheerful character to the release which they bring.¹ The Saturnalia of the Romans and our modern carnival agree in this essential feature with the festivals of primitive people, which usually end in debaucheries of every kind and the transgression of what are at other times the most sacred commandments. But the ego ideal comprises the sum of all the limitations in which the ego has to acquiesce, and for that reason the abrogation of the ideal would necessarily be a magnificent festival for the ego, which might then once again feel satisfied with itself.²

There is always a feeling of triumph when something in the ego coincides with the ego ideal. And the sense of guilt (as well as the sense of inferiority) can also be understood as an expression of tension between the ego and the ego ideal.

¹ *Totem and Taboo*.

² Trotter traces repression back to the herd instinct. It is a translation of this into another form of expression rather than a contradiction when I say in my paper on narcissism that 'for the ego the formation of an ideal would be the conditioning factor of repression'.

It is well known that there are people the general colour of whose mood oscillates periodically from an excessive depression through some kind of intermediate state to an exalted sense of well-being. These oscillations appear in very different degrees of amplitude, from what is just noticeable to those extreme instances which, in the shape of melancholia and mania, make the most tormenting or disturbing inroads upon the life of the person concerned. In typical cases of this cyclical depression external precipitating causes do not seem to play any decisive part; as regards internal motives, nothing more, or nothing else is to be found in these patients than in all others. It has consequently become the custom to consider these cases as not being psychogenic. We shall refer presently to those other exactly similar cases of cyclical depression which *can* easily be traced back to mental traumas.

Thus the foundation of these spontaneous oscillations of mood is unknown; we are without insight into the mechanism of the displacement of a melancholia by a mania. So we are free to suppose that these patients are people in whom our conjecture might find an actual application - their ego ideal might be temporarily resolved into their ego after having previously ruled it with especial strictness.

Let us keep to what is clear: On the basis of our analysis of the ego it cannot be doubted that in cases of mania the ego and the ego ideal have fused together, so that the person, in a mood of triumph and self-satisfaction, disturbed by no self-criticism, can enjoy the abolition of his inhibitions, his feelings of consideration for others, and his self-reproaches. It is not so obvious, but nevertheless very probable, that the misery of the melancholic is the expression of a sharp conflict between the two agencies of his ego, a conflict in which the ideal, in an excess of sensitiveness, relentlessly exhibits its condemnation of the ego in delusions of inferiority and in self-depreciation. The only question is whether we are to look for the causes of these altered relations between the ego and the ego ideal in the periodic rebellions, which we have postulated above, against the new institution, or whether we are to make other circumstances responsible for them.

A change into mania is not an indispensable feature of the symptomatology of melancholic depression. There are simple melancholias, some in single and some in recurrent attacks, which never show this development.

On the other hand there are melancholias in which the precipitating cause clearly plays an aetiological part. They are those which occur after the loss of a loved object, whether by death or as the result of circumstances which have necessitated the withdrawal of the libido from the object. A psychogenic melancholia of this sort can end in mania, and this cycle can be repeated several times, just as easily as in a case which appears to be spontaneous. Thus the state of things is somewhat obscure, especially as only a few forms and cases of melancholia have been submitted to psycho-analytic investigation.¹ So far we only understand those cases in which the object is given up because it has shown itself unworthy of love. It is then set up again inside the ego, by means of identification, and severely condemned by the ego ideal. The reproaches and attacks directed towards the object come to light in the shape of melancholic self-reproaches.²

A melancholia of this kind, too, may end in a change into mania; so that the possibility of this happening represents a feature which is independent of the other characteristics of the clinical picture.

Nevertheless I see no difficulty in assigning to the factor of the periodic rebellion of the ego against the ego ideal a share in both kinds of melancholia, the psychogenic as well as the spontaneous. In the spontaneous kind it may be supposed that the ego ideal is inclined to display a peculiar strictness, which then results automatically in its temporary suspension. In the psychogenic kind the ego would be incited to rebellion by ill-treatment on the part of its ideal - an ill-treatment which it encounters when there has been identification with a rejected object.

¹ Cf. Abraham (1912).

² To speak more accurately, they conceal themselves behind the reproaches directed towards the subject's own ego, and lend them the fixity, tenacity, and imperativeness which characterize the self-reproaches of a melancholic.

XII

POSTSCRIPT

In the course of the enquiry which has just been brought to a provisional end we came across a number of side-paths which we avoided pursuing in the first instance but in which there was much that offered us promises of insight. We propose now to take up a few of the points that have been left on one side in this way.

A. The distinction between identification of the ego with an object and replacement of the ego ideal by an object finds an interesting illustration in the two great artificial groups which we began by studying, the army and the Christian Church.

It is obvious that a soldier takes his superior, that is, in fact, the leader of the army, as his ideal, while he identifies himself with his equals, and derives from this community of their egos the obligations for giving mutual help and for sharing possessions which comradeship implies. But he becomes ridiculous if he tries to identify himself with the general. The soldier in *Wallensteins Lager* laughs at the sergeant for this very reason:

Wie er räuspert und wie er spuckt,
Das habt ihr ihm glücklich abgeguckt!

It is otherwise in the Catholic Church. Every Christian loves Christ as his ideal and feels himself united with all other Christians by the tie of identification. But the Church requires more of him. He has also to identify himself with Christ and love all other Christians as Christ loved them. At both points, therefore, the Church requires that the position of the libido which is given by group formation should be supplemented. Identification has to be added where object-choice has taken place, and object-love where there is identification. This addition evidently goes beyond the constitution of the group. One can be a good Christian and yet be far from the idea of putting oneself in Christ's place and of having like him an all-embracing love for mankind. One need not think oneself capable, weak mortal that one is, of the Saviour's largeness of soul and strength of love. But this further development in the distribution of libido in the group is probably the factor upon which Christianity bases its claim to have reached a higher ethical level.

B. We have said that it would be possible to specify the point in the mental development of mankind at which the advance from group psychology to individual psychology was achieved also by the individual members of the group.¹

For this purpose we must return for a moment to the scientific myth of the father of the primal horde. He was later on exalted into the creator of the world, and with justice, for he had produced all the sons who composed the first group. He was the ideal of each one of them, at once feared and honoured, a fact which led later to the idea of taboo. These many individuals eventually banded themselves together, killed him and cut him in pieces. None of the group of victors could take his place, or, if one of them did, the battles began afresh, until they understood that they must all renounce their father's heritage. They then formed the totemic community of brothers, all with equal rights and united by the totem prohibitions which were to preserve and to expiate the memory of the murder. But the dissatisfaction with what had been achieved still remained, and it became the source of new developments. The persons who were united in this group of brothers gradually came towards a revival of the old state of things at a new level. The male became once more the chief of a family, and broke down the prerogatives of the gynaecocracy which had become established during the fatherless period. As a compensation for this he may at that time have acknowledged the mother deities, whose priests were castrated for the mother's protection, after the example that had been given by the father of the primal horde. And yet the new family was only a shadow of the old one; there were numbers of fathers and each one was limited by the rights of the others.

¹ What follows at this point was written under the influence of an exchange of ideas with Otto Rank. See also Rank (1922).

It was then, perhaps, that some individual, in the exigency of his longing, may have been moved to free himself from the group and take over the father's part. He who did this was the first epic poet; and the advance was achieved in his imagination. This poet disguised the truth with lies in accordance with his longing. He invented the heroic myth. The hero was a man who by himself had slain the father - the father who still appeared in the myth as a totemic monster. Just as the father had been the boy's first ideal, so in the hero who aspires to the father's place the poet now created the first ego ideal. The transition to the hero was probably afforded by the youngest son, the mother's favourite, whom she had protected from paternal jealousy, and who, in the era of the primal horde, had been the father's successor. In the lying poetic fancies of prehistoric times the woman, who had been the prize of battle and the temptation to murder, was probably turned into the active seducer and instigator to the crime.

The hero claims to have acted alone in accomplishing the deed, which certainly only the horde as a whole would have ventured upon. But, as Rank has observed, fairy tales have preserved clear traces of the facts which were disavowed. For we often find in them that the hero who has to carry out some difficult task (usually the youngest son, and not infrequently one who has represented himself to the father-substitute as being stupid, that is to say, harmless) - we often find, then, that this hero can carry out his task only by the help of a crowd of small animals, such as bees or ants. These would be the brothers in the primal horde, just as in the same way in dream symbolism insects or vermin signify brothers and sisters (contemptuously, considered as babies). Moreover every one of the tasks in myths and fairy tales is easily recognizable as a substitute for the heroic deed.

The myth, then, is the step by which the individual emerges from group psychology. The first myth was certainly the psychological, the hero myth; the explanatory nature myth must have followed much later. The poet who had taken this step and had in this way set himself free from the group in his imagination, is nevertheless able (as Rank has further observed) to find his way back to it in reality. For he goes and relates to the group his hero's deeds which he has invented. At bottom this hero is no one but himself. Thus he lowers himself to the level of reality, and raises his hearers to the level of imagination. But his hearers understand the poet, and, in virtue of their having the same relation of longing towards the primal father, they can identify themselves with the hero.¹

The lie of the heroic myth culminates in the deification of the hero. Perhaps the deified hero may have been earlier than the Father God and may have been a precursor to the return of the primal father as a deity. The series of gods, then, would run chronologically: Mother Goddess-Hero-Father God. But it is only with the elevation of the never-forgotten primal father that the deity acquires the features that we still recognize in him to-day.²

¹ Cf. Hanns Sachs (1920).

² In this brief exposition I have made no attempt to bring forward any of the material existing in legends, myths, fairy tales, the history of manners, etc., in support of the construction.

C. A great deal has been said in this paper about directly sexual instincts and those that are inhibited in their aims, and it may be hoped that this distinction will not meet with too much resistance. But a detailed discussion of the question will not be out of place, even if it only repeats what has to a great extent already been said before.

The development of the libido in children has made us acquainted with the first but also the best example of sexual instincts which are inhibited in their aims. All the feelings which a child has towards its parents and those who look after it pass by an easy transition into the wishes which give expression to the child's sexual impulsions. The child claims from these objects of its love all the signs of affection which it knows of; it wants to kiss them, touch them, and look at them; it is curious to see their genitals, and to be with them when they perform their intimate excretory functions; it promises to marry its mother or nurse - whatever it may understand by marriage; it proposes to itself to bear its father a child, etc. Direct observation, as well as the subsequent analytic investigation of the residues of childhood, leave no doubt as to the complete fusion of tender and jealous feelings and of sexual intentions, and show us in what a fundamental way the child makes the person it loves into the object of all its still not properly centred sexual trends.¹

¹ Cf. my *Three Essays* (1905d).

This first configuration of the child's love, which in typical cases takes the shape of the Oedipus complex, succumbs, as we know, from the beginning of the period of latency onwards to a wave of repression. Such of it as is left over shows itself as a purely affectionate emotional tie, relating to the same people, but no longer to be described as 'sexual'. Psycho-analysis, which illuminates the depths of mental life, has no difficulty in showing that the sexual ties of the earliest years of childhood also persist, though repressed and unconscious. It gives us courage to assert that wherever we come across an affectionate feeling it is successor to a completely 'sensual' object-tie with the person in question or rather with that person's prototype (or *imago*). It cannot indeed disclose to us without a special investigation whether in a given case this former complete sexual current still exists under repression or whether it has already been exhausted. To speak still more precisely: it is quite certain that this current is still there as a form and possibility, and can always be cathected and put into activity again by means of regression; the only question is (and it cannot always be answered) what degree of cathexis and operative force it still has at the present moment. Equal care must be taken in this connection to avoid two sources of error - the Scylla of underestimating the importance of the repressed unconscious, and the Charybdis of judging the normal entirely by the standards of the pathological.

A psychology which will not or cannot penetrate the depths of what is repressed regards affectionate emotional ties as being invariably the expression of impulsions which have no sexual aim, even though they are derived from impulsions which have such an aim.¹

¹ Hostile feelings are doubtless a little more complicated in their construction.

We are justified in saying that they have been diverted from these sexual aims, even though there is some difficulty in giving a description of such a diversion of aim which will conform to the requirements of metapsychology. Moreover, those instincts which are inhibited in their aims always preserve some few of their original sexual aims; even an affectionate devotee, even a friend or an admirer, desires the physical proximity and the sight of the person who is now loved only in the 'Pauline' sense. If we choose, we may recognize in this diversion of aim a beginning of the *sublimation* of the sexual instincts, or on the other hand we may fix the limits of sublimation at some more distant point. Those sexual instincts which are inhibited in their aims have a great functional advantage over those which are uninhibited. Since they are not capable of really complete satisfaction, they are especially adapted to create permanent ties; while those instincts which are directly sexual incur a loss of energy each time they are satisfied, and must wait to be renewed by a fresh accumulation of sexual libido, so that meanwhile the object may have been changed. The inhibited instincts are capable of any degree of admixture with the uninhibited; they can be transformed back into them, just as they arose out of them. It is well known how easily erotic wishes develop out of emotional relations of a friendly character, based upon appreciation and admiration (compare Molière's 'Kiss me for the love of Greek'), between a master and a pupil, between a performer and a delighted listener, and especially in the case of women. In fact the growth of emotional ties of this kind, with their purposeless beginnings, provides a much frequented pathway to sexual object-choice. Pfister, in his *Frömmigkeit des Grafen von Zinzendorf* (1910), has given an extremely clear and certainly not an isolated example of how easily even an intense religious tie can revert to ardent sexual excitement. On the other hand it is also very usual for directly sexual impulsions, short-lived in themselves, to be transformed into a lasting and purely affectionate tie; and the consolidation of a passionate love marriage rests to a large extent upon this process.

We shall naturally not be surprised to hear that the sexual impulsions that are inhibited in their aims arise out of the directly sexual ones when internal or external obstacles make the sexual aims unattainable. The repression during the period of latency is an internal obstacle of this kind - or rather one which has become internal. We have assumed that the father of the primal horde owing to his sexual intolerance compelled all his sons to be abstinent, and thus forced them into ties that were inhibited in their aims, while he reserved for himself freedom of sexual enjoyment and in this way remained without ties. All the ties upon which a group depends are of the character of instincts that are inhibited in their aims. But here we have approached the discussion of a new subject, which deals with the relation between directly sexual instincts and the formation of groups.

D. The last two remarks will have prepared us for finding that directly sexual impulsions are unfavourable to the formation of groups. In the history of the development of the family there have also, it is true, been group relations of sexual love (group marriages); but the more important sexual love became for the ego, and the more it developed the characteristics of being in love, the more urgently it required to be limited to two people - *una cum uno* - as is prescribed by the nature of the genital aim. Polygamous inclinations had to be content to find satisfaction in a succession of changing objects.

Two people coming together for the purpose of sexual satisfaction, in so far as they seek for solitude, are making a demonstration against the herd instinct, the group feeling. The more they are in love, the more completely they suffice for each other. Their rejection of the group's influence is expressed in the shape of a sense of shame. Feelings of jealousy of the most extreme violence are summoned up in order to protect the choice of a sexual object from being encroached upon by a group tie. It is only when the affectionate, that is, personal, factor of a love relation gives place entirely to the sensual one, that it is possible for two people to have sexual intercourse in the presence of others or for there to be simultaneous sexual acts in a group, as occurs at an orgy. But at that point a regression has taken place to an early stage in sexual relations, at which being in love as yet played no part, and all sexual objects were judged to be of equal value, somewhat in the sense of Bernard Shaw's malicious aphorism to the effect that being in love means greatly exaggerating the difference between one woman and another.

There are abundant indications that being in love only made its appearance late on in the sexual relations between men and women; so that the opposition between sexual love and group ties is also a late development. Now it may seem as though this assumption were incompatible with our myth of the primal family. For it was after all by their love for their mothers and sisters that the mob of brothers was, as we have supposed, driven to parricide; and it is difficult to imagine this love as being anything but undivided and primitive - that is, as an intimate union of the affectionate and sensual. But further consideration resolves this objection to our theory into a confirmation of it. One of the reactions to the parricide was after all the institution of totemic exogamy, the prohibition of any sexual relation with those women of the family who had been tenderly loved since childhood. In this way a wedge was driven in between a man's affectionate and sensual feelings, one still firmly fixed in his erotic life to-day.¹ As a result of this exogamy the sensual needs of men had to be satisfied with strange and unloved women.

¹ See Freud, (1912*d*).

In the great artificial groups, the Church and the army, there is no room for woman as a sexual object. The love relation between men and women remains outside these organizations. Even where groups are formed which are composed of both men and women the distinction between the sexes plays no part. There is scarcely any sense in asking whether the libido which keeps groups together is of a homosexual or of a heterosexual nature, for it is not differentiated according to the sexes, and particularly shows a complete disregard for the aims of the genital organization of the libido.

Even in a person who has in other respects become absorbed in a group, the directly sexual impulsions preserve a little of his individual activity. If they become too strong they disintegrate every group formation. The Catholic Church had the best of motives for recommending its followers to remain unmarried and for imposing celibacy upon its priests; but falling in love has often driven even priests to leave the Church. In the same way love for women breaks through the group ties of race, of national divisions, and of the social class system, and it thus produces important effects as a factor in civilization. It seems certain that homosexual love is far more compatible with group ties, even when it takes the shape of uninhibited sexual impulsions - a remarkable fact, the explanation of which might carry us far.

The psycho-analytic investigation of the psychoneuroses has taught us that their symptoms are to be traced back to directly sexual impulsions which are repressed but still remain active. We can complete this formula by adding - 'or, to aim-inhibited impulsions, whose inhibition has not been entirely successful or has made room for a return to the repressed sexual aim'. It is in accordance with this that a neurosis should make its victim asocial and should remove him from the usual group formations. It may be said that a neurosis has the same disintegrating effect upon a group as being in love. On the other hand it appears that where a powerful impetus has been given to group formation neuroses may diminish and, at all events temporarily, disappear. Justifiable attempts have also been made to turn this antagonism between neuroses and group formation to therapeutic account. Even those who do not regret the disappearance of religious illusions from the civilized world of to-day will admit that so long as they were in force they offered those who were bound by them the most powerful protection against the danger of neurosis. Nor is it hard to discern that all the ties that bind people to mystico-religious or philosophico-religious sects and communities are expressions of crooked cures of all kinds of neuroses. All of this is correlated with the contrast between directly sexual impulsions and those which are inhibited in their aims.

If he is left to himself, a neurotic is obliged to replace by his own symptom formations the great group formations from which he is excluded. He creates his own world of imagination for himself, his own religion, his own system of delusions, and thus recapitulates the institutions of humanity in a distorted way which is clear evidence of the dominating part played by the directly sexual impulsions.¹

¹ See *Totem and Taboo*, towards the end of the second essay.

E. In conclusion, we will add a comparative estimate, from the standpoint of the libido theory, of the states with which we have been concerned, of being in love, of hypnosis, of group formation, and of neurosis.

Being in love is based on the simultaneous presence of directly sexual impulsions and of sexual impulsions that are inhibited in their aims, while the object draws a part of the subject's narcissistic ego-libido to itself. It is a condition in which there is only room for the ego and the object.

Hypnosis resembles being in love in being limited to these two persons, but it is based entirely on sexual impulsions that are inhibited in their aims and puts the object in the place of the ego ideal.

The group multiplies this process; it agrees with hypnosis in the nature of the instincts which hold it together, and in the replacement of the ego ideal by the object; but to this it adds identification with other individuals, which was perhaps originally made possible by their having the same relation to the object.

Both states, hypnosis and group formation, are an inherited deposit from the phylogenesis of the human libido - hypnosis in the form of a predisposition, and the group, besides this, as a direct survival. The replacement of the directly sexual impulsions by those that are inhibited in their aims promotes in both states a separation between the ego and the ego ideal, a separation with which a beginning has already been made in the state of being in love.

Neurosis stands outside this series. It also is based upon a peculiarity in the development of the human libido - the twice repeated start made by the directly sexual function, with an intervening period of latency.¹ To this extent it resembles hypnosis and group formation in having the character of a regression, which is absent from being in love. It makes its appearance wherever the advance from directly sexual instincts to those that are inhibited in their aims has not been wholly successful; and it represents a *conflict* between those portions of the instincts which have been received into the ego after having passed through this development and those portions of them which, springing from the repressed unconscious, strive - as do other, completely repressed, instinctual impulses - to attain direct satisfaction. Neuroses are extraordinarily rich in content, for they embrace all possible relations between the ego and the object - both those in which the object is retained and others in which it is abandoned or erected inside the ego itself - and also the conflicting relations between the ego and its ego ideal.

THE PSYCHOGENESIS OF A CASE OF HOMOSEXUALITY IN A WOMAN
(1920)

Intentionally left blank

THE PSYCHOGENESIS OF A CASE OF HOMOSEXUALITY IN A WOMAN

I

Homosexuality in women, which is certainly not less common than in men, although much less glaring, has not only been ignored by the law, but has also been neglected by psycho-analytic research. The narration of a single case, not too pronounced in type, in which it was possible to trace its origin and development in the mind with complete certainty and almost without a gap may, therefore, have a certain claim to attention. If this presentation of it furnishes only the most general outlines of the various events concerned and of the conclusions reached from a study of the case, while suppressing all the characteristic details on which the interpretation is founded, this limitation is easily to be explained by the medical discretion necessary in discussing a recent case.

A beautiful and clever girl of eighteen, belonging to a family of good standing, had aroused displeasure and concern in her parents by the devoted adoration with which she pursued a certain 'society lady' who was about ten years older than herself. The parents asserted that, in spite of her distinguished name, this lady was nothing but a *cocotte*. It was well known, they said, that she lived with a friend, a married woman, and had intimate relations with her, while at the same time she carried on promiscuous affairs with a number of men. The girl did not contradict these evil reports, but neither did she allow them to interfere with her worship of the lady, although she herself was by no means lacking in a sense of decency and propriety. No prohibitions and no supervision hindered the girl from seizing every one of her rare opportunities of being together with her beloved, of ascertaining all her habits, of waiting for her for hours outside her door or at a tram-halt, of sending her gifts of flowers, and so on. It was evident that this one interest had swallowed up all others in the girl's mind. She did not trouble herself any further with educational studies, thought nothing of social functions or girlish pleasures, and kept up relations only with a few girl friends who could help her in the matter or serve as confidantes. The parents could not say to what lengths their daughter had gone in her relations with the questionable lady, whether the limits of devoted admiration had already been exceeded or not. They had never remarked in their daughter any interest in young men, nor pleasure in their attentions, while, on the other hand, they were sure that her present attachment to a woman was only a continuation, in a more marked degree, of a feeling she had displayed of recent years for other members of her own sex which had already aroused her father's suspicion and anger.

There were two details of her behaviour, in apparent contrast with each other, that most especially vexed her parents. On the one hand, she did not scruple to appear in the most frequented streets in the company of her undesirable friend, being thus quite neglectful of her own reputation; while, on the other hand, she disdained no means of deception, no excuses and no lies that would make meetings with her possible and cover them. She thus showed herself too open in one respect and full of deceitfulness in the other. One day it happened, indeed, as was sooner or later inevitable in the circumstances, that the father met his daughter in the company of the lady, about whom he had come to know. He passed them by with an angry glance which boded no good. Immediately afterwards the girl rushed off and flung herself over a wall down the side of a cutting on to the suburban railway line which ran close by. She paid for this undoubtedly serious attempt at suicide with a considerable time on her back in bed, though fortunately little permanent damage was done. After her recovery she found it easier to get her own way than before. The parents did not dare to oppose her with so much determination, and the lady, who up till then had received her advances coldly, was moved by such an unmistakable proof of serious passion and began to treat her in a more friendly manner.

About six months after this episode the parents sought medical advice and entrusted the physician with the task of bringing their daughter back to a normal state of mind. The girl's attempted suicide had evidently shown them that strong disciplinary measures at home were powerless to overcome her disorder. Before going further, however, it will be desirable to deal separately with the attitudes of her father and of her mother to the matter. The father was an earnest, worthy man, at bottom very tender-hearted, but he had to some extent estranged his children by the sternness he had adopted towards them. His treatment of his only daughter was too much influenced by consideration for his wife. When he first came to know of his daughter's homosexual tendencies he flew into a rage and tried to suppress them by threats. At that time perhaps he hesitated between different, though equally distressing, views - regarding her either as vicious, as degenerate, or as mentally afflicted. Even after the attempted suicide he did not achieve the lofty resignation shown by one of our medical colleagues who remarked of a similar irregularity in his own family: 'Well, it's just a misfortune like any other.' There was something about his daughter's homosexuality that aroused the deepest bitterness in him, and he was determined to combat it with all the means in his power. The low estimation in which psycho-analysis is so generally held in Vienna did not prevent him from turning to it for help. If this way failed he still had in reserve his strongest counter-measure: a speedy marriage was to awaken the natural instincts of the girl and stifle her unnatural tendencies.

The mother's attitude towards the girl was not so easy to grasp. She was still a youngish woman, who was evidently unwilling to give up her own claims to attractiveness. All that was clear was that she did not take her daughter's infatuation so tragically as did the father, nor was she so incensed at it. She had even for some time enjoyed her daughter's confidence concerning her passion. Her opposition to it seemed to have been aroused mainly by the harmful publicity with which the girl displayed her feelings. She had herself suffered for some years from neurotic troubles and enjoyed a great deal of consideration from her husband; she treated her children in quite different ways, being decidedly harsh towards her daughter and over-indulgent to her three sons, the youngest of whom had been born after a long interval and was then not yet three years old. It was not easy to ascertain anything more definite about her character, for, owing to motives that will only later become intelligible, the patient was always reserved in what she said about her mother, whereas in regard to her father there was no question of this.

To a physician who was to undertake psycho-analytic treatment of the girl there were many grounds for misgiving. The situation he had to deal with was not the one that analysis demands, in which alone it can demonstrate its effectiveness. As is well known, the ideal situation for analysis is when someone who is otherwise his own master is suffering from an inner conflict which he is unable to resolve alone, so that he brings his trouble to the analyst and begs for his help. The physician then works hand in hand with one portion of the pathologically divided personality, against the other party in the conflict. Any situation which differs from this is to a greater or lesser degree unfavourable for psycho-analysis and adds fresh difficulties to the internal ones already present. Situations like that of a prospective house-owner who orders an architect to build him a villa to his own tastes and requirements, or of a pious donor who commissions an artist to paint a sacred picture in the corner of which is to be a portrait of himself in adoration, are at bottom incompatible with the conditions necessary for psycho-analysis. Thus, it constantly happens that a husband instructs the physician as follows: 'My wife suffers from nerves, and for that reason gets on badly with me; please cure her, so that we may lead a happy married life again.' But often enough it turns out that such a request is impossible to fulfil - that is to say, the physician cannot bring about the result for which the husband sought the treatment. As soon as the wife is freed from her neurotic inhibitions she sets about getting a separation, for her neurosis was the sole condition under which the marriage could be maintained. Or else parents expect one to cure their nervous and unruly child. By a healthy child they mean one who never causes his parents trouble, and gives them nothing but pleasure. The physician may succeed in curing the child, but after that it goes its own way all the more decidedly, and the parents are now far more dissatisfied than before. In short, it is not a matter of indifference whether someone comes to analysis of his own accord or because he is brought to it - whether it is he himself who desires to be changed, or only his relatives, who love him (or who might be expected to love him).

Further unfavourable features in the present case were the facts that the girl was not in any way ill (she did not suffer from anything in herself, nor did she complain of her condition) and that the task to be carried out did not consist in resolving a neurotic conflict but in converting one variety of the genital organization of sexuality into the other. Such an achievement - the removal of genital inversion or homosexuality - is in my experience never an easy matter. On the contrary, I have found success possible only in specially favourable circumstances, and even then the success essentially consisted in making access to the opposite sex (which had hitherto been barred) possible to a person restricted to homosexuality, thus restoring his full bisexual functions. After that it lay with him to choose whether he wished to abandon the path that is banned by society, and in some cases he has done so. One must remember that normal sexuality too depends upon a restriction in the choice of object. In general, to undertake to convert a fully developed homosexual into a heterosexual does not offer much more prospect of success than the reverse, except that for good practical reasons the latter is never attempted.

The number of successes achieved by psycho-analytic treatment of the various forms of homosexuality, which incidentally are manifold, is indeed not very striking. As a rule the homosexual is not able to give up the object which provides him with pleasure, and one cannot convince him that if he made the change he would rediscover in the other object the pleasure that he has renounced, and such components of the instinct of self-preservation prove themselves too weak in the struggle against the sexual impulses. One then soon discovers his secret plan, namely, to obtain from the striking failure of his attempt a feeling of satisfaction that he has done everything possible against his abnormality, to which he can now resign himself with an easy conscience. The case is somewhat different when consideration for beloved parents and relatives has been the motive for his attempt to be cured. Here there really are libidinal impulses present which may put forth energies opposed themselves to the homosexual choice of object; but their strength is rarely sufficient. It is only where the homosexual fixation has not yet become strong enough, or where there are considerable rudiments and vestiges of a heterosexual choice of object, i.e. in a still oscillating or in a definitely bisexual organization, that one may make a more favourable prognosis for psycho-analytic therapy.

For these reasons I refrained altogether from holding out to the parents any prospect of their wish being fulfilled. I merely said I was prepared to study the girl carefully for a few weeks or months, so as then to be able to pronounce how far a continuation of the analysis would be likely to influence her. In quite a number of cases, indeed, an analysis falls into two clearly distinguishable phases. In the first, the physician procures from the patient the necessary information, makes him familiar with the premises and postulates of psycho-analysis, and unfolds to him the reconstruction of the genesis of his disorder as deduced from the material brought up in the analysis. In the second phase the patient himself gets hold of the material put before him; he works on it, recollects what he can of the apparently repressed memories, and tries to repeat the rest as if he were in some way living it over again. In this way he can confirm, supplement, and correct the inferences made by the physician. It is only during this work that he experiences, through overcoming resistances, the inner change aimed at, and acquires for himself the convictions that make him independent of the physician's authority. These two phases in the course of the analytic treatment are not always sharply divided from each other; this can only happen when the resistance obeys certain conditions. But when this is so, one may bring up as an analogy the two stages of a journey. The first comprises all the necessary preparations, to-day so complicated and hard to effect, before, ticket in hand, one can at last go on to the platform and secure a seat in the train. One then has the right, and the possibility, of travelling into a distant country; but after all these preliminary exertions one is not yet there - indeed, one is not a single mile nearer to one's goal. For this to happen one has to make the journey itself from one station to the other, and this part of the performance may well be compared with the second phase of the analysis.

The course of the present patient's analysis followed this two-phased pattern, but it was not continued beyond the beginning of the second phase. A special constellation of the resistance made it possible, nevertheless, to gain full confirmation of my constructions, and to obtain an adequate insight on broad lines into the way in which her inversion had developed. But before relating the findings of the analysis I must deal with a few points which have either been touched upon already by myself or which will have roused special interest in the reader.

I had made the prognosis partly dependent on how far the girl had succeeded in satisfying her passion. The information I obtained during the analysis seemed favourable in this respect. With none of the objects of her adoration had the patient enjoyed anything beyond a few kisses and embraces; her genital chastity, if one may use such a phrase, had remained intact. As for the *demi-mondaine* who had roused her most recent and by far her strongest emotions, she had always been treated coldly by her and never been allowed any greater favour than to kiss her hand. She was probably making a virtue of necessity when she kept insisting on the purity of her love and her physical repulsion against the idea of any sexual intercourse. But perhaps she was not altogether wrong when she boasted of her wonderful beloved that, being of good birth as she was, and forced into her present position only by adverse family circumstances, she had preserved, in spite of her situation, much nobility of character. For the lady used to recommend the girl every time they met to withdraw her affection from herself and from women in general, and she had persistently rejected the girl's advances up to the time of the attempted suicide.

A second point, which I at once tried to investigate, concerned any possible motives in the girl herself which might serve as a support for psycho-analytic treatment. She did not try to deceive me by saying that she felt any urgent need to be freed from her homosexuality. On the contrary, she said she could not conceive of any other way of being in love, but she added that for her parents' sake she would honestly help in the therapeutic attempt, for it pained her very much to be the cause of so much grief to them. To begin with, I could not but take this, too, as a propitious sign; for I could not guess the unconscious affective attitude that lay concealed behind it. What came to light later in this connection decisively influenced the course taken by the analysis and determined its premature conclusion.

Readers unversed in psycho-analysis will long have been awaiting an answer to two other questions. Did this homosexual girl show physical characteristics plainly belonging to the opposite sex, and did the case prove to be one of congenital or acquired (later-developed) homosexuality?

I am aware of the importance attaching to the first of these questions. But one should not exaggerate it and allow it to overshadow the fact that sporadic secondary characteristics of the opposite sex are very often present in normal individuals, and that well-marked physical characteristics of the opposite sex may be found in persons whose choice of object has undergone no change in the direction of inversion; in other words, that in both sexes *the degree of physical hermaphroditism is to a great extent independent of psychical hermaphroditism*. In modification of these statements it must be added that this independence is more evident in men than women, where bodily and mental traits belonging to the opposite sex are apt to coincide. Still I am not in a position to give a satisfactory answer to the first of our questions about my patient. The psycho-analyst customarily forgoes a thorough physical examination of his patients in certain cases. Certainly there was no obvious deviation from the feminine physical type, nor any menstrual disturbance. The beautiful and well-made girl had, it is true, her father's tall figure, and her facial features were sharp rather than soft and girlish, traits which might be regarded as indicating a physical masculinity. Some of her intellectual attributes also could be connected with masculinity: for instance, her acuteness of comprehension and her lucid objectivity, in so far as she was not dominated by her passion. But these distinctions are conventional rather than scientific. What is certainly of greater importance is that in her behaviour towards her love-object she had throughout assumed the masculine part: that is to say, she displayed the humility and the sublime overvaluation of the sexual object so characteristic of the male lover, the renunciation of all narcissistic satisfaction, and the preference for being the lover rather than the beloved. She had thus not only chosen a feminine love-object, but had also developed a masculine attitude towards that object.

The second question, whether this was a case of congenital or acquired homosexuality, will be answered by the whole history of the patient's abnormality and its development. The study of this will show how far this question is a fruitless and inapposite one.

II

After this highly discursive introduction I am only able to present a very concise summary of the sexual history of the case under consideration. In childhood the girl had passed through the normal attitude characteristic of the feminine Oedipus complex¹ in a way that was not at all remarkable, and had later also begun to substitute for her father a brother slightly older than herself. She did not remember any sexual traumas in early life, nor were any discovered by the analysis. Comparison of her brother's genital organs and her own, which took place about the beginning of the latency period (at five years old or perhaps a little earlier), left a strong impression on her and had far-reaching after-effects. There were very few signs pointing to infantile masturbation, or else the analysis did not go far enough to throw light on this point. The birth of a second brother when she was between five and six years old exercised no special influence upon her development. During the pre-pubertal years at school she gradually became acquainted with the facts of sex, and she received this knowledge with mixed feelings of lasciviousness and frightened aversion, in a way which may be called normal and was not exaggerated in degree. This amount of information about her seems meagre enough, nor can I guarantee that it is complete. It may be that the history of her youth was much richer in experiences; I do not know. As I have already said, the analysis was broken off after a short time, and therefore yielded an anamnesis not much more reliable than the other anamneses of homosexuals, which there is good cause to question. Further, the girl had never been neurotic, and came to the analysis without even one hysterical symptom, so that opportunities for investigating the history of her childhood did not present themselves so readily as usual.

At the age of thirteen to fourteen she displayed a tender and, according to general opinion, exaggeratedly strong affection for a small boy, not quite three years old, whom she used to see regularly in a children's playground. She took to the child so warmly that in consequence a lasting friendship grew up between herself and his parents. One may infer from this episode that at that time she was possessed of a strong desire to be a mother herself and to have a child. However, after a short time she grew indifferent to the boy, and began to take an interest in mature, but still youthful, women. The manifestations of this interest soon brought upon her a severe chastisement at the hands of her father.

¹ I do not see any advance or gain in the introduction of the term 'Electra complex', and do not advocate its use.

It was established beyond all doubt that this change occurred simultaneously with a certain event in the family, and one may therefore look to this for some explanation of the change. Before it happened, her libido was concentrated on a maternal attitude, while afterwards she became a homosexual attracted to mature women, and remained so ever since. The event which is so significant for our understanding of the case was a new pregnancy of her mother's, and the birth of a third brother when she was about sixteen.

The position of affairs which I shall now proceed to lay bare is not a product of my inventive powers; it is based on such trustworthy analytic evidence that I can claim objective validity for it. It was in particular a series of dreams, interrelated and easy to interpret, that decided me in favour of its reality.

The analysis revealed beyond all shadow of doubt that the lady-love was a substitute for - her mother. It is true that the lady herself was not a mother, but then she was not the girl's first love. The first objects of her affection after the birth of her youngest brother were really mothers, women between thirty and thirty-five whom she had met with their children during summer holidays or in the family circle of acquaintances in town. Motherhood as a *sine qua non* in her love-object was later on given up, because that precondition was difficult to combine in real life with another one, which grew more and more important. The specially intense bond with her latest love had still another basis which the girl discovered quite easily one day. Her lady's slender figure, severe beauty, and downright manner reminded her of the brother who was a little older than herself. Her latest choice corresponded, therefore, not only to her feminine but also to her masculine ideal; it combined satisfaction of the homosexual tendency with that of the heterosexual one. It is well known that analysis of male homosexuals has in numerous cases revealed the same combination, which should warn us not to form too simple a conception of the nature and genesis of inversion, and to keep in mind the universal bisexuality of human beings.¹

¹ Cf. Sadger (1914).

But how are we to understand the fact that it was precisely the birth of a child who came late in the family (at a time when the girl herself was already mature and had strong wishes of her own) that moved her to bestow her passionate tenderness upon the woman who gave birth to this child, i. e. her own mother, and to express that feeling towards a substitute for her mother? From all that we know we should have expected just the opposite. In such circumstances mothers with daughters of nearly a marriageable age usually feel embarrassed in regard to them, while the daughters are apt to feel for their mothers a mixture of compassion, contempt and envy which does nothing to increase their tenderness for them. The girl we are considering had in any case altogether little cause to feel affection for her mother. The latter, still youthful herself, saw in her rapidly developing daughter an inconvenient competitor; she favoured the sons at her expense, limited her independence as much as possible, and kept an especially strict watch against any close relation between the girl and her father. A yearning from the beginning for a kinder mother would, therefore, have been quite intelligible, but why it should have flared up just then, and in the form of a consuming passion, is hard to understand.

The explanation is as follows. It was just when the girl was experiencing the revival of her infantile Oedipus complex at puberty that she suffered her great disappointment. She became keenly conscious of the wish to have a child, and a male one; that what she desired was her *father's* child and an image of *him*, her consciousness was not allowed to know. And what happened next? It was not *she* who bore the child, but her unconsciously hated rival, her mother. Furiously resentful and embittered, she turned away from her father and from men altogether. After this first great reverse she forswore her womanhood and sought another goal for her libido.

In doing so she behaved just as many men do who after a first distressing experience turn their backs forever upon the faithless female sex and become woman-haters. It is related of one of the most attractive and unfortunate princely figures of our time that he became a homosexual because the lady he was engaged to marry betrayed him with another man. I do not know whether this is true historically, but an element of psychological truth lies behind the rumour. In all of us, throughout life, the libido normally oscillates between male and female objects; the bachelor gives up his men friends when he marries, and returns to club-life when married life has lost its savour. Naturally, when the swing-over is fundamental and final, we suspect the presence of some special factor which definitely favours one side or the other, and which perhaps has only waited for the appropriate moment in order to turn the choice of object in its direction.

After her disappointment, therefore, this girl had entirely repudiated her wish for a child, her love of men, and the feminine role in general. It is evident that at this point a number of very different things might have happened. What actually happened was the most extreme case. She changed into a man and took her mother in place of her father as the object of her love.¹ Her relation to her mother had certainly been ambivalent from the beginning, and it proved easy to revive her earlier love for her mother and with its help to bring about an overcompensation for her current hostility towards her. Since there was little to be done with the real mother, there arose from this transformation of feeling the search for a substitute mother to whom she could become passionately attached.²

¹ It is by no means rare for a love-relation to be broken off through a process of identification on the part of the lover with the loved object, a process equivalent to a kind of regression to narcissism. After this has been accomplished, it is easy in making a fresh choice of object to direct the libido to a member of the sex opposite to that of the earlier choice.

² The displacements of the libido here described are doubtless familiar to every analyst from investigation of the anamneses of neurotics. With the latter, however, they occur in early childhood, at the time of the early efflorescence of erotic life; with our patient, who was in no way neurotic, they took place in the first years following puberty, though, incidentally, they were just as completely unconscious. Perhaps one day this temporal factor may turn out to be of great importance.

There was, in addition, a practical motive for this change, derived from her real relations with her mother, which served as a gain from her illness. The mother herself still attached great value to the attentions and the admiration of men. If, then, the girl became homosexual and left men to her mother (in other words, 'retired in favour of' her mother), she would remove something which had hitherto been partly responsible for her mother's dislike.¹

This libidinal position of the girl's, thus arrived at, was greatly reinforced as soon as she perceived how much it displeased her father. After she had been punished for her over-affectionate attitude to a woman she realized how she could wound her father and take revenge on him. Henceforth she remained homosexual out of defiance against her father. Nor did she scruple to lie to him and to deceive him in every way. Towards her mother, indeed, she was only so far deceitful as was necessary to prevent her father from knowing things. I had the impression that her behaviour followed the principle of the talion: 'Since you have betrayed me, you must put up with my betraying you.' Nor can I come to any other conclusion about the striking lack of caution displayed by this otherwise exceedingly shrewd girl. She *wanted* her father to know occasionally of her relations with the lady, otherwise she would be deprived of the satisfaction of her keenest desire - namely, revenge. So she saw to this by showing herself openly in the company of her adored one, by walking with her in the streets near her father's place of business, and the like. This maladroitness, moreover, was by no means unintentional. It was remarkable, too, that both parents behaved as if they understood their daughter's secret psychology. The mother was tolerant, as though she appreciated her daughter's 'retirement' as a favour to her; the father was furious, as though he realized the deliberate revenge directed against himself.

The girl's inversion, however, received its final reinforcement when she found in her 'lady' an object which promised to satisfy not only her homosexual trends, but also that part of her heterosexual libido which was still attached to her brother.

¹ As 'retiring in favour of someone else' has not previously been mentioned among the causes of homosexuality, or in the mechanism of libidinal fixation in general, I will adduce here another analytic observation of the same kind which has a special feature of interest. I once knew two twin brothers, both of whom were endowed with strong libidinal impulses. One of them was very successful with women, and had innumerable affairs with women and girls. The other went the same way at first, but it became unpleasant for him to be trespassing on his brother's preserves, and, owing to the likeness between them, to be mistaken for him on intimate occasions; so he got out of the difficulty by becoming homosexual. He left the women to his brother, and thus retired in his favour. Another time I treated a youngish man, an artist, unmistakably bisexual in disposition, in whom the homosexual trend had come to the fore simultaneously with a disturbance in his work. He fled from both women and work together. The analysis, which was able to bring him back to both, showed that fear of his father was the most powerful psychical motive for both the disturbances, which were really renunciations. In his imagination all women belonged to his father, and he sought refuge in men out of submission, so as to retire from the conflict with his father. Such a motivation of the homosexual object-choice must be by no means uncommon; in the primaeval ages of the human race all women presumably belonged to the father and head of the primal horde.

Among brothers and sisters who are not twins this 'retiring' plays a great part in other spheres as well as in that of erotic choice. For example, an elder brother studies music and is admired for it; the younger, far more gifted musically, soon gives up his own musical studies, in spite of his fondness for it, and cannot be persuaded to touch an instrument again. This is only one example of a very frequent occurrence, and investigation of the motives leading to this 'retirement' rather than to open rivalry discloses very complicated conditions in the mind.

III

Linear presentation is not a very adequate means of describing complicated mental processes going on in different layers of the mind. I am therefore obliged to pause in the discussion of the case and treat more fully and deeply some of the points brought forward above.

I mentioned the fact that in her behaviour to her adored lady the girl had adopted the characteristic masculine type of love. Her humility and her tender lack of pretensions, '*che poco spera e nulla chiede*', her bliss when she was allowed to accompany the lady a little way and to kiss her hand on parting, her joy when she heard her praised as beautiful (while any recognition of her own beauty by another person meant nothing at all to her), her pilgrimages to places once visited by the loved one, the silence of all more sensual wishes - all these little traits in her resembled the first passionate adoration of a youth for a celebrated actress whom he regards as far above him, to whom he scarcely dares lift his bashful eyes. The correspondence with 'a special type of choice of object made by men' that I have described elsewhere (1910*h*), whose special features I traced to attachment to the mother, held good even to the smallest details. It may seem remarkable that she was not in the least repelled by the bad reputation of her beloved, although her own observations sufficiently confirmed the truth of such rumours. She was after all a well-brought-up and modest girl, who had avoided sexual adventures for herself, and who regarded coarsely sensual satisfactions as unaesthetic. But already her first passions had been for women who were not celebrated for specially strict propriety. The first protest her father made against her love-choice had been evoked by the pertinacity with which she sought the company of a film actress at a summer resort. Moreover, in all these affairs it had never been a question of women who had any reputation for homosexuality, and who might, therefore, have offered her some prospect of homosexual satisfaction; on the contrary, she illogically courted women who were coquettes in the ordinary sense of the word, and she rejected without hesitation the willing advances made by a homosexual friend of her own age. For her, the bad reputation of her 'lady', however, was positively a 'necessary condition for love'. All that is enigmatic in this attitude vanishes when we remember that in the case too of the *masculine* type of object-choice derived from the mother it is a necessary condition that the loved object should be in some way or other 'of bad repute' sexually - someone who really may be called a *cocotte*. When the girl learnt later how far her adored lady deserved this description and that she lived simply by giving her bodily favours, her reaction took the form of great compassion and of phantasies and plans for 'rescuing' her beloved from these ignoble circumstances. We were struck by the same urge to 'rescue' in the men of the type referred to above, and in my description of it I have tried to give the analytic derivation of this urge.

We are led into quite another realm of explanation by the analysis of the attempt at suicide, which I must regard as seriously intended, and which, incidentally, considerably improved her position both with her parents and with the lady she loved. She went for a walk with her one day in a part of the town and at an hour at which she was not unlikely to meet her father on his way from his office. So it turned out. Her father passed them in the street and cast a furious look at her and her companion, about whom he had by that time come to know. A few moments later she flung herself into the railway cutting. The explanation she gave of the immediate reasons determining her decision sounded quite plausible. She had confessed to the lady that the man who had given them such an irate glance was her father, and that he had absolutely forbidden their friendship. The lady became incensed at this and ordered the girl to leave her then and there, and never again to wait for her or to address her - the affair must now come to an end. In her despair at having thus lost her loved one for ever, she wanted to put an end to herself. The analysis, however, was able to disclose another and deeper interpretation behind the one she gave, which was confirmed by the evidence of her own dreams. The attempted suicide was, as might have been expected, determined by two other motives besides the one she gave: it was the fulfilment of a punishment (self-punishment), and the fulfilment of a wish. As the latter it meant the attainment of the very wish which, when frustrated, had driven her into homosexuality - namely, the wish to have a child by her father, for now she 'fell' through her father's fault.¹ The fact that at that moment the lady had spoken in just the same terms as her father, and had uttered the same prohibition, forms the connecting link between this deep interpretation and the superficial one of which the girl herself was conscious. From the point of view of self-punishment the girl's action shows us that she had developed in her unconscious strong death-wishes against one or other of her parents - perhaps against her father, out of revenge for impeding her love, but more probably against her mother too, when she was pregnant with the little brother. For analysis has explained the enigma of suicide in the following way: probably no one finds the mental energy required to kill himself unless, in the first place, in doing so he is at the same time killing an object with whom he has identified himself, and, in the second place, is turning against himself a death-wish which had been directed against someone else. Nor need the regular discovery of these unconscious death-wishes in those who have attempted suicide surprise us (any more than it ought to make us think that it confirms our deductions), since the unconscious of all human beings is full enough of such death-wishes, even against those they love.² Since the girl identified herself with her mother, who should have died at the birth of the child denied to herself, this punishment-fulfilment itself was once again a wish-fulfilment. Finally, the discovery that several quite different motives, all of great strength, must have co-operated to make such a deed possible is only in accordance with what we should expect.

¹ That the various methods of suicide can represent sexual wish-fulfilments has long been known to all analysts. (To poison oneself = to become pregnant; to drown - to bear a child; to throw oneself from a height = to be delivered of a child.)

² Cf. 'Thoughts for the Times on War and Death' (1915b).

In the girl's account of her conscious motives the father did not figure at all; there was not even any mention of fear of his anger. In the motives laid bare by the analysis, on the other hand, he played the principal part. Her relation to her father had the same decisive importance for the course and outcome of the analytic treatment, or rather, analytic exploration. Behind her pretended consideration for her parents, for whose sake she had been willing to make the attempt to be transformed, lay concealed her attitude of defiance and revenge against her father which held her fast to her homosexuality. Secure under this cover, the resistance set a considerable region free to analytic investigation. The analysis went forward almost without any signs of resistance, the patient participating actively with her intellect, though absolutely tranquil emotionally. Once when I expounded to her a specially important part of the theory, one touching her nearly, she replied in an inimitable tone, 'How very interesting', as though she were a *grande dame* being taken over a museum and glancing through her lorgnon at objects to which she was completely indifferent. The impression one had of her analysis was not unlike that of a hypnotic treatment, where the resistance has in the same way withdrawn to a certain boundary line, beyond which it proves to be unconquerable. The resistance very often pursues similar tactics - Russian tactics, as they might be called - in cases of obsessional neurosis. For a time, consequently, these cases yield the clearest results and permit a deep insight into the causation of the symptoms. But presently one begins to wonder how it is that such marked progress in analytic understanding can be unaccompanied by even the slightest change in the patient's compulsions and inhibitions, until at last one perceives that everything that has been accomplished is subject to a mental reservation of doubt, and that behind this protective barrier the neurosis can feel secure. 'It would be all very fine', thinks the patient, often quite consciously, 'if I were obliged to believe what the man says, but there is no question of that, and so long as this is so I need change nothing.' Then, when one comes to close quarters with the motives for this doubt, the fight with the resistances breaks out in earnest.

In the case of our patient, it was not doubt but the affective factor of revenge against her father that made her cool reserve possible, that divided the analysis into two distinct phases, and rendered the results of the first phase so complete and perspicuous. It seemed, further, as though nothing resembling a transference to the physician had been effected. That, however, is of course absurd, or, at least, is a loose way of expressing things. For some kind of relation to the analyst must come into being, and this relation is almost always transferred from an infantile one. In reality she transferred to me the sweeping repudiation of men which had dominated her ever since the disappointment she had suffered from her father. Bitterness against men is as a rule easy to gratify upon the physician; it need not evoke any violent emotional manifestations, it simply expresses itself by rendering futile all his endeavours and - by clinging to the illness. I know from experience how difficult it is to make a patient understand just precisely this mute kind of symptomatic behaviour and to make him aware of this latent, and often exceedingly strong, hostility without endangering the treatment. As soon, therefore, as I recognized the girl's attitude to her father, I broke off the treatment and advised her parents that if they set store by the therapeutic procedure it should be continued by a woman doctor. The girl had in the meanwhile promised her father that at any rate she would give up seeing the 'lady', and I do not know whether my advice, the reasons for which are obvious, will be followed.

There was a single piece of material in the course of this analysis which I could regard as a positive transference, as a greatly weakened revival of the girl's original passionate love for her father. Even this manifestation was not quite free from other motives, but I mention it because it brings up, in another direction, an interesting problem of analytic technique. At a certain period, not long after the treatment had begun, the girl brought a series of dreams which, distorted according to rule and couched in the usual dream-language, could nevertheless be easily translated with certainty. Their content, when interpreted, was, however, remarkable. They anticipated the cure of the inversion through the treatment, expressed her joy over the prospects in life that would then be opened before her, confessed her longing for a man's love and for children, and so might have been welcomed as a gratifying preparation for the desired change. The contradiction between them and the girl's utterances in waking life at the time was very great. She did not conceal from me that she meant to marry, but only in order to escape from her father's tyranny and to follow her true inclinations undisturbed. As for the husband, she remarked rather contemptuously, she would easily deal with him, and besides, one could have sexual relations with a man and a woman at one and the same time, as the example of the adored lady showed. Warned through some slight impression or other, I told her one day that I did not believe these dreams, that I regarded them as false or hypocritical, and that she intended to deceive me just as she habitually deceived her father. I was right; after I had made this clear, this kind of dream ceased. But I still believe that, beside the intention to mislead me, the dreams partly expressed the wish to win my favour; they were also an attempt to gain my interest and my good opinion - perhaps in order to disappoint me all the more thoroughly later on.

I can imagine that to point out the existence of lying dreams of this kind, 'obliging' dreams, will arouse a positive storm of helpless indignation in some readers who call themselves analysts. 'What!' they will exclaim, 'the unconscious, the real centre of our mental life, the part of us that is so much nearer the divine than our poor consciousness - it too can lie! Then how can we still build on the interpretations of analysis and the accuracy of our findings?' To which one must reply that the recognition of these lying dreams does not constitute any shattering novelty. I know, indeed, that the craving of mankind for mysticism is ineradicable, and that it makes ceaseless efforts to win back for mysticism the territory it has been deprived of by *The Interpretation of Dreams*, but surely in the case under consideration everything is simple enough. A dream is not the 'unconscious'; it is the form into which a thought left over from preconscious, or even from conscious, waking life, can, thanks to the favouring state of sleep, be recast. In the state of sleep this thought has been reinforced by unconscious wishful impulses and has thus experienced distortion through the dream-work, which is determined by the mechanisms prevailing in the unconscious. With our dreamer, the intention to mislead me, just as she did her father, certainly emanated from the preconscious, and may indeed have been conscious; it could come to expression by entering into connection with the unconscious wishful impulse to please her father (or father-substitute), and in this way it created a lying dream. The two intentions, to betray and to please her father, originated in the same complex; the former resulted from the repression of the latter, and the later one was brought back by the dream-work to the earlier one. There can therefore be no question of any devaluation of the unconscious, nor of a shattering of our confidence in the results of analysis.

I cannot neglect this opportunity of expressing for once my astonishment that human beings can go through such great and important moments of their erotic life without noticing them much, sometimes even, indeed, without having the faintest suspicion of their existence, or else, having become aware of those moments, deceive themselves so thoroughly in their judgement of them. This happens not only under neurotic conditions, where we are familiar with the phenomenon, but seems also to be common enough in ordinary life. In the present case, for example, a girl develops a sentimental adoration for women, which her parents at first find merely vexatious and hardly take seriously; she herself knows quite well that she is very much occupied with these relationships, but still she experiences few of the sensations of intense love until a particular frustration is followed by a quite excessive reaction, which shows everyone concerned that they have to do with a consuming passion of elemental strength. Nor had the girl ever perceived anything of the state of affairs which was a necessary preliminary to the outbreak of this mental storm. In other cases, too, we come across girls or women in a state of severe depression, who on being asked for a possible cause of their condition tell us that they have, it is true, had a slight feeling for a certain person, but that it was nothing deep and that they soon got over it when they had to give it up. And yet it was this renunciation, apparently so easily borne, that became the cause of serious mental disturbance. Again, we come across men who have passed through casual love-affairs and realize only from the subsequent effects that they had been passionately in love with the person whom they had apparently regarded lightly. One is also amazed at the unexpected results that may follow an artificial abortion, the killing of an unborn child, which had been decided upon without remorse and without hesitation. It must be admitted that poets are right in liking to portray people who are in love without knowing it, or uncertain whether they do love, or who think that they hate when in reality they love. It would seem that the information received by our consciousness about our erotic life is especially liable to be incomplete, full of gaps, or falsified. Needless to say, in this discussion I have not omitted to allow for the part played by subsequent forgetting.

IV

I now come back, after this digression, to the consideration of my patient's case. We have made a survey of the forces which led the girl's libido from the normal Oedipus attitude into that of homosexuality, and of the psychological paths traversed by it in the process. Most important in this respect was the impression made by the birth of her little brother, and we might from this be inclined to classify the case as one of late-acquired inversion.

But at this point we become aware of a state of things which also confronts us in many other instances in which light has been thrown by psycho-analysis on a mental process. So long as we trace the development from its final outcome backwards, the chain of events appears continuous, and we feel we have gained an insight which is completely satisfactory or even exhaustive. But if we proceed the reverse way, if we start from the premises inferred from the analysis and try to follow these up to the final result, then we no longer get the impression of an inevitable sequence of events which could not have been otherwise determined. We notice at once that there might have been another result, and that we might have been just as well able to understand and explain the latter. The synthesis is thus not so satisfactory as the analysis; in other words, from a knowledge of the premises we could not have foretold the nature of the result.

It is very easy to account for this disturbing state of affairs. Even supposing that we have a complete knowledge of the aetiological factors that decide a given result, nevertheless what we know about them is only their quality, and not their relative strength. Some of them are suppressed by others because they are too weak, and they therefore do not affect the final result. But we never know beforehand which of the determining factors will prove the weaker or the stronger. We only say at the end that those which succeeded must have been the stronger. Hence the chain of causation can always be recognized with certainty if we follow the line of analysis, whereas to predict it along the line of synthesis is impossible.

We do not, therefore, mean to maintain that every girl who experiences a disappointment such as this of the longing for love that springs from the Oedipus attitude at puberty will necessarily on that account fall a victim to homosexuality. On the contrary, other kinds of reaction to this trauma are undoubtedly commoner. If so, however, there must have been present in this girl special factors that turned the scale, factors outside the trauma, probably of an internal nature. Nor is there any difficulty in pointing them out.

It is well known that even in a normal person it takes a certain time before the decision in regard to the sex of the love object is finally made. Homosexual enthusiasms, exaggeratedly strong friendships tinged with sensuality, are common enough in both sexes during the first years after puberty. This was also so with our patient, but in her these tendencies undoubtedly showed themselves to be stronger, and lasted longer, than with others. In addition, these presages of later homosexuality had always occupied her *conscious* life, while the attitude arising from the Oedipus complex had remained *unconscious* and had appeared only in such signs as her tender behaviour to the little boy. As a school-girl she had been for a long time in love with a strict and unapproachable mistress, obviously a substitute mother. She had taken a specially lively interest in a number of young mothers long before her brother's birth and therefore all the more certainly long before the first reprimand from her father. From very early years, therefore, her libido had flowed in two currents, the one on the surface being one that we may unhesitatingly designate as homosexual. This latter was probably a direct and unchanged continuation of an infantile fixation on her mother. Possibly the analysis described here actually revealed nothing more than the process by which, on an appropriate occasion, the deeper heterosexual current of libido, too, was deflected into the manifest homosexual one.

The analysis showed, further, that the girl had brought along with her from her childhood a strongly marked 'masculinity complex'. A spirited girl, always ready for romping and fighting, she was not at all prepared to be second to her slightly older brother; after inspecting his genital organs she had developed a pronounced envy for the penis, and the thoughts derived from this envy still continued to fill her mind. She was in fact a feminist; she felt it to be unjust that girls should not enjoy the same freedom as boys, and rebelled against the lot of woman in general. At the time of the analysis the idea of pregnancy and child-birth was disagreeable to her, partly, I surmise, on account of the bodily disfigurement connected with them. Her girlish narcissism had fallen back on this defence,¹ and ceased to express itself as pride in her good looks. Various clues indicated that she must formerly have had strong exhibitionist and scopophilic tendencies. Anyone who is anxious that the claims of acquired as opposed to hereditary factors should not be under-estimated in aetiology will call attention to the fact that the girl's behaviour, as described above, was exactly what would follow from the combined effect in a person with a strong mother-fixation of the two influences of her mother's neglect and her comparison of her genital organs with her brother's. It is possible here to attribute to the impress of the operation of external influence in early life something which one would have liked to regard as a constitutional peculiarity. On the other hand, a part even of this acquired disposition (if it was really acquired) has to be ascribed to inborn constitution. So we see in practice a continual mingling and blending of what in theory we should try to separate into a pair of opposites - namely, inherited and acquired characters.

If the analysis had come to an earlier, still more premature end, it might have led to the view that this was a case of late acquired homosexuality, but as it is, a consideration of the material impels us to conclude that it is rather a case of congenital homosexuality which, as usual, became fixed and unmistakably manifest only in the period following puberty. Each of these classifications does justice only to one part of the state of affairs ascertainable by observation, but neglects the other. It would be best not to attach too much value to this way of stating the problem.

¹ Cf. Kriemhilde's admission in the *Nibelungenlied*.

The literature of homosexuality usually fails to distinguish clearly enough between the questions of the choice of object on the one hand, and of the sexual characteristics and sexual attitude of the subject on the other, as though the answer to the former necessarily involved the answers to the latter. Experience, however, proves the contrary: a man with predominantly male characteristics and also masculine in his erotic life may still be inverted in respect to his object, loving only men instead of women. A man in whose character feminine attributes obviously predominate, who may, indeed, behave in love like a woman, might be expected, from this feminine attitude, to choose a man for his love-object; but he may nevertheless be heterosexual, and show no more inversion in respect to his object than an average normal man. The same is true of women; here also mental sexual character and object-choice do not necessarily coincide. The mystery of homosexuality is therefore by no means so simple as it is commonly depicted in popular expositions - 'a feminine mind, bound therefore to love a man, but unhappily attached to a masculine body; a masculine mind, irresistibly attracted by women, but, alas! imprisoned in a feminine body'. It is instead a question of three sets of characteristics, namely -

Physical sexual characters
(physical hermaphroditism)

Mental sexual characters
(masculine or feminine attitude)

Kind of object-choice

which, up to a certain point, vary independently of one another, and are met with in different individuals in manifold permutations. Tendentious literature has obscured our view of this interrelationship by putting into the foreground, for practical reasons, the third feature (the kind of object-choice), which is the only one that strikes the layman, and in addition by exaggerating the closeness of the association between this and the first feature. Moreover, it blocks the way to a deeper insight into all that is uniformly designated as homosexuality, by rejecting two fundamental facts which have been revealed by psycho-analytic investigation. The first of these is that homosexual men have experienced a specially strong fixation on their mother; the second, that, in addition to their manifest heterosexuality, a very considerable measure of latent or unconscious homosexuality can be detected in all normal people. If these findings are taken into account, then, clearly, the supposition that nature in a freakish mood created a 'third sex' falls to the ground.

It is not for psycho-analysis to solve the problem of homosexuality. It must rest content with disclosing the psychical mechanisms that resulted in determining the object-choice, and with tracing back the paths from them to the instinctual dispositions. There its work ends, and it leaves the rest to biological research, which has recently brought to light, through Steinach's¹ experiments, such very important results concerning the influence exerted by the first set of characteristics mentioned above upon the second and third. Psycho-analysis has a common basis with biology, in that it presupposes an original bisexuality in human beings (as in animals). But psycho-analysis cannot elucidate the intrinsic nature of what in conventional or in biological phraseology is termed 'masculine' and 'feminine': it simply takes over the two concepts and makes them the foundation of its work. When we attempt to reduce them further, we find masculinity vanishing into activity and femininity into passivity, and that does not tell us enough. I have already tried to explain how far we may reasonably expect, or how far experience has already proved, that the work of elucidation which is part of the task of analysis furnishes us with the means of effecting a modification of inversion. When one compares the extent to which we can influence it with the remarkable transformations that Steinach has effected in some cases by his operations, it does not make a very imposing impression. But it would be premature, or a harmful exaggeration, if at this stage we were to indulge in hopes of a 'therapy' of inversion that could be generally applied. The cases of male homosexuality in which Steinach has been successful fulfilled the condition, which is not always present, of a very patent physical 'hermaphroditism'. Any analogous treatment of female homosexuality is at present quite obscure. If it were to consist in removing what are probably hermaphroditic ovaries, and in grafting others, which are hoped to be of a single sex, there would be little prospect of its being applied in practice. A woman who has felt herself to be a man, and has loved in masculine fashion, will hardly let herself be forced into playing the part of a woman, when she must pay for this transformation, which is not in every way advantageous, by renouncing all hope of motherhood.

PSYCHO-ANALYSIS AND TELEPATHY

INTRODUCTORY

We are not destined, so it seems, to devote ourselves quietly to the extension of our science. Scarcely have we triumphantly repulsed two attacks - one of which sought to deny once more what we had brought to light and only offered us in exchange the theme of disavowal, while the other tried to persuade us that we had mistaken the nature of what we had found and might with advantage take something else in its place - scarcely, then, do we feel ourselves safe from these enemies, when another peril has arisen. And this time it is something tremendous, something elemental, which threatens not us alone but our enemies, perhaps, still more.

It no longer seems possible to keep away from the study of what are known as 'occult' phenomena - of facts, that is, that profess to speak in favour of the real existence of psychical forces other than the human and animal minds with which we are familiar, or that seem to reveal the possession by those minds of faculties hitherto unrecognized. The impetus towards such an investigation seems irresistibly strong. During this last brief vacation I have three times had occasion to refuse to associate myself with newly founded periodicals concerned with these studies. Nor is there much doubt as to the origin of this trend. It is a part expression of the loss of value by which everything has been affected since the world catastrophe of the Great War, a part of the tentative approach to the great revolution towards which we are heading and of whose extent we can form no estimate; but no doubt it is also an attempt at compensation, at making up in another, a supermundane, sphere for the attractions which have been lost by life on this earth. Some, indeed, of the proceedings of the exact sciences themselves may have contributed to this development. The discovery of radium has confused no less than it has advanced the possibilities of explaining the physical world; and the knowledge that has been so very recently acquired of what is called the theory of relativity has had the effect upon many of those who admire without comprehending it of diminishing their belief in the objective trustworthiness of science. You will remember that not long ago Einstein himself took occasion to protest against such misunderstanding.

It does not follow as a matter of course that an intensified interest in occultism must involve a danger to psycho-analysis. We should, on the contrary, be prepared to find reciprocal sympathy between them. They have both experienced the same contemptuous and arrogant treatment by official science. To this day psycho-analysis is regarded as savouring of mysticism, and its unconscious is looked upon as one of the things between heaven and earth which philosophy refuses to dream of. The numerous suggestions made to us by occultists that we should co-operate with them show that they would like to treat us as half belonging to them and that they count on our support against the pressure of exact authority. Nor, on the other hand, has psycho-analysis any interest in going out of its way to defend that authority, for it itself stands in opposition to everything that is conventionally restricted, well-established and generally accepted. Not for the first time would it be offering its help to the obscure but indestructible surmises of the common people against the obscurantism of educated opinion. Alliance and co-operation between analysts and occultists might thus appear both plausible and promising.

But if we look closer, difficulties begin to emerge. The immense majority of occultists are not driven by a desire for knowledge or by a sense of shame that science has so long refused to take cognizance of what are indisputable problems or by a desire to conquer this new sphere of phenomena. They are, on the contrary, convinced believers who are looking for confirmation and for something that will justify them in openly confessing their faith. But the faith which they first adopt themselves and then seek to impose on other people is either the old religious faith which has been pushed into the background by science in the course of human development, or another one even closer to the superseded convictions of primitive peoples. Analysts, on the other hand, cannot repudiate their descent from exact science and their community with its representatives. Moved by an extreme distrust of the power of human wishes and of the temptations of the pleasure principle, they are ready, for the sake of attaining some fragment of objective certainty, to sacrifice everything - the dazzling brilliance of a flawless theory, the exalted consciousness of having achieved a comprehensive view of the universe, and the mental calm brought about by the possession of extensive grounds for expedient and ethical action. In place of all these, they are content with fragmentary pieces of knowledge and with basic hypotheses lacking preciseness and ever open to revision. Instead of waiting for the moment when they will be able to escape from the constraint of the familiar laws of physics and chemistry, they hope for the emergence of more extensive and deeper-reaching natural laws, to which they are ready to submit. Analysts are at bottom incorrigible mechanists and materialists, even though they seek to avoid robbing the mind and spirit of their still unrecognized characteristics. So, too, they embark on the investigation of occult phenomena only because they expect in that way finally to exclude the wishes of mankind from material reality.

In view of this difference between their mental attitudes co-operation between analysts and occultists offers small prospect of gain. The analyst has his own province of work, which he must not abandon: the unconscious element of mental life. If in the course of his work he were to be on the watch for occult phenomena, he would be in danger of overlooking everything that more nearly concerned him. He would be surrendering the impartiality, the lack of prejudices and prepossessions, which have formed an essential part of his analytic armour and equipment. If occult phenomena force themselves on him in the same way in which others do, he will evade them no more than he evades the others. This would appear to be the only plan of behaviour consistent with the activity of an analyst.

By self-discipline the analyst can defend himself against one danger - the subjective one of allowing his interest to be drawn away on to occult phenomena. As regards the *objective* danger, the situation is different. There is little doubt that if attention is directed to occult phenomena the outcome will very soon be that the occurrence of a number of them will be confirmed; and it will probably be a very long time before an acceptable theory covering these new facts can be arrived at. But the eagerly attentive onlookers will not wait so long. At the very first confirmation the occultists will proclaim the triumph of their views. They will carry over an acceptance of one phenomenon on to all the rest and will extend belief in the phenomena to belief in whatever explanations are easiest and most to their taste. They will be ready to employ the methods of scientific enquiry only as a ladder to raise them over the head of science. Heaven help us if they climb to such a height! There will be no scepticism from the surrounding spectators to make them hesitate, there will be no popular outcry to bring them to a halt. They will be hailed as liberators from the burden of intellectual bondage, they will be joyfully acclaimed by all the credulity lying ready to hand since the infancy of the human race and the childhood of the individual. There may follow a fearful collapse of critical thought, of determinist standards and of mechanistic science. Will it be possible for scientific method, by a ruthless insistence on the magnitude of the forces, the masses and qualities of the material concerned, to prevent this collapse?

It is a vain hope to suppose that analytic work, precisely because it relates to the mysterious unconscious, will be able to escape such a collapse in values as this. If spiritual beings who are the intimate friends of human enquirers can supply ultimate explanations of everything, no interest can be left over for the laborious approaches to unknown mental forces made by analytic research. So, too, the methods of analytic technique will be abandoned if there is a hope of getting into direct touch with the operative spirits by means of occult procedures, just as habits of patient humdrum work are abandoned if there is a hope of growing rich at a single blow by means of a successful speculation. We have heard during the war of people who stood half-way between two hostile nations, belonging to one by birth and to the other by choice and domicile; it was their fate to be treated as enemies first by one side and then, if they were lucky enough to escape, by the other. Such might equally be the fate of psycho-analysis. However, one must put up with one's fate whatever it may be; and psycho-analysis will somehow or other come to terms with hers.

Let us return to the present situation, to our immediate task. In the course of the last few years I have made a few observations which I shall not hold back - at all events from the circle that is closest to me. A dislike of falling in with what is to-day a prevailing current, a dread of distracting interest from psycho-analysis and the total absence of any veil of discretion over what I have to say - all these combine as motives for withholding my remarks from a wider public. My material can lay claim to two advantages which are rarely present. In the first place it is exempt from the uncertainties and doubts to which most of the observations of the occultists are prone; and in the second place it only develops its convincing force after it has been worked over analytically. It consists, I should mention, of only two cases of a similar character; a third case, of another kind and open to a different assessment, is only added by way of appendix. The first two cases, which I shall now report at length, are concerned with events of the same sort - namely, with prophecies made by professional fortune-tellers which did *not* come true. In spite of this, these prophecies made an extraordinary impression on the people to whom they were announced, so that their relation to the future cannot be their essential point. Anything that may contribute to their explanation, as well as anything that throws doubt on their evidential force, will be extremely welcome to me. My personal attitude to the material remains unenthusiastic and ambivalent.

I

A few years before the war, a young man from Germany came to me to be analysed. He complained of being unable to work, of having forgotten his past life and of having lost all interest. He was a student of philosophy at Munich and was preparing for his final examination. Incidentally, he was a highly educated, rather sly young man, rascally in a childish way, and the son of a financier, who, as emerged later, had successfully remoulded a colossal amount of anal erotism. When I asked him whether there was really nothing he could remember about his life or his sphere of interest, he recalled the plot of a novel he had sketched out, which was laid in Egypt during the reign of Amenophis IV and in which an important part was played by a particular ring. We took this novel as a starting-point; the ring turned out to be a symbol of marriage, and from there we succeeded in reviving all his memories and interests. We found that his breakdown had been the result of a great act of mental self-discipline on his part. He had an only sister a few years his junior, to whom he was wholeheartedly and quite undisguisedly devoted. 'Why is it we can't get married?' they had often asked each other. But their affection had never gone beyond the point permissible between brothers and sisters.

A young engineer had fallen in love with the sister. His love was reciprocated by her but did not meet with the approval of her strict parents. In their trouble the two young lovers turned to the brother for help. He gave their cause his support, made it possible for them to correspond, arranged for them to meet while he was at home on vacation, and eventually persuaded the parents to give their consent to an engagement and marriage. During the time of the engagement there was a highly suspicious occurrence. The brother took his future brother-in-law to climb the Zugspitze and himself acted as guide. They lost their way on the mountain, ran into trouble and only with difficulty avoided a fall. The patient offered little objection to my interpretation of this adventure as an attempted murder and suicide. It was a few months after his sister's marriage that the young man started analysis.

After some six or nine months he had completely regained his ability to work, and broke off the analysis in order to take his examination and write his dissertation. A year or more later he returned - now a Ph. D.- to resume his analysis, because, as he said, psycho-analysis had an interest for him as a philosopher which extended beyond therapeutic success. I know it was in October that he started again, and it was a few weeks later that, in some connection or other, he told me the following story.

There lived in Munich a fortune-teller who enjoyed a great reputation. The Bavarian princes used to visit her when they had any undertaking in mind. All that she required was to be supplied with a date. (I omitted to enquire whether this had to include the date of the *year*.) It was understood that the date was that of the birth of some particular person, but she did not ask whose. Having been given this date, she would consult her astrological books, make long calculations and finally utter a prophecy about the person concerned. In the previous March my patient resolved to visit the fortune-teller. He presented her with the date of his brother-in-law's birth, without, of course, mentioning his name or betraying the fact that he had him in mind. The oracle pronounced as follows: 'The person in question will die next July or August of crayfish- or oyster-poisoning.' After telling me this, my patient exclaimed: 'It was marvellous!'

I could not understand this and contradicted him vigorously: 'What do you see in it that's marvellous? You've been working with me now for several weeks, and if your brother-in-law had really died you would have told me long ago. So he must be alive. The prophecy was made in March and was to be fulfilled during the height of the summer. It's November now, so it has *not* been fulfilled. What do you find so wonderful in that?

'No doubt it has not come true,' he replied. 'But the remarkable thing about it is this. My brother-in-law is passionately fond of crayfish and oysters and so on, and *last* August he really did have an attack of crayfish-poisoning and almost died of it.' The matter was not further discussed.

Let us now consider this case.

I believe in the narrator's truthfulness. He is entirely trustworthy and is at present lecturer in philosophy at K----. I can think of no motive which could have induced him to bamboozle me. The story was an incidental one and served no ulterior purpose; nothing further emerged from it and no conclusions were drawn from it. He had no intention of persuading me of the existence of occult mental phenomena; and indeed I had an impression that he was not at all clear about the significance of his experience. I myself was so much struck - to tell the truth, so disagreeably affected - that I omitted to make any analytic use of his tale.

And the observation seems to me equally unobjectionable from another point of view. It is certain that the fortune-teller was not acquainted with the man who put the question. But consider what a degree of intimacy with an acquaintance would be necessary before one could recognize the date of his brother-in-law's birthday. On the other hand, you will no doubt all agree with me in offering the most obstinate resistance to the possibility that so detailed an event as falling ill of crayfish poisoning could be inferred from the date of the subject's birth by the help of any tables or formulae whatever. Do not forget how many people are born on the same day. Is it credible that the similarity of the futures of people born on the same day can be carried down to such details as this? I therefore venture to exclude the astrological calculations entirely from the discussion; I believe the fortune-teller might have adopted some other procedure without affecting the outcome of the interrogation. Accordingly, we can also, so it seems to me, leave the fortune-teller (or, as we may say straight out, the 'medium') quite out of account as a possible source of deception.

If you grant the genuineness and truth of this observation, its explanation will be near. And we at once find - and this is the case with the majority of these phenomena - that its explanation on an occult basis is remarkably adequate and covers what has to be explained completely, except that it is so unsatisfying in itself. It is impossible that the knowledge that this man - born on the day in question - had had an attack of crayfish-poisoning could have been present in the fortune-teller's mind; nor can she have arrived at that knowledge from her tables and calculations. It was, however, present in the mind of her questioner. The event becomes completely explicable if we are ready to assume that the knowledge was transferred from him to the supposed prophetess - by some unknown method which excluded the means of communication familiar to us. That is to say, we must draw the inference that there is such a thing as thought-transference. The fortune-teller's astrological activities would in that case have performed the function of diverting her own psychical forces and occupying them in a harmless way, so that she could become receptive and accessible to the effects upon her of her client's thoughts - so that she could become a true 'medium'. We have found similar distracting contrivances employed (for instance, in the case of jokes) where there is a question of securing a more automatic discharge for some mental process.

The application of analysis to this case does more than this, however; it further increases its significance. It teaches us that what has been communicated by this means of induction from one person to another is not merely a chance piece of indifferent knowledge. It shows that an extraordinarily powerful wish harboured by one person and standing in a special relation to his consciousness has succeeded, with the help of a second person, in finding conscious expression in a slightly disguised form - just as the invisible end of the spectrum reveals itself to the senses on a light-sensitive plate as a coloured extension. It seems possible to reconstruct the young man's train of thought after the illness and recovery of the brother-in-law who was his hated rival: 'Well, he's got over it this time; but he won't give up his dangerous taste on that account, and let's hope that next time it will be the end of him.' It was this 'let's hope' that was changed into the prophecy. I could quote a parallel to this from a dream (dreamt by another person), in which a prophecy was part of the subject-matter. The analysis of the dream showed that the content of the prophecy coincided with the fulfilment of a wish.

I cannot simplify my statement by describing my patient's death-wish against his brother-in-law as an unconscious, repressed one. For it had been made conscious during the treatment the year before and the consequences which had followed from its repression had yielded to the treatment. But it still persisted, and, though it was no longer pathogenic, it was sufficiently intense. It might be described as a 'suppressed' wish.

II

In the city of F--- a child grew up who was the eldest of a family of five, all girls. The youngest was ten years younger than herself; she once dropped this child out of her arms when it was a baby; later she called it 'her child'. Her mother was older than her father and not an agreeable person. Her father - and it was not in years only that he was the younger - saw a lot of the little girls and impressed them by his many dexterities. Unfortunately he was not impressive in any other way: he was incompetent at business and was unable to support the family without help from relatives. The eldest girl became at an early age the repository of all the worries that arose from his lack of earning power.

Once she had left behind the rigid and passionate character of her childhood, she grew up into a regular mirror of all the virtues. Her high moral feelings were accompanied by a narrowly limited intelligence. She became a teacher in an elementary school and was much respected. The timid homage paid to her by a young relation who was a music teacher left her unmoved. No other man had hitherto attracted her notice.

One day a relative of her mother's appeared on the scene, considerably older than she was, but still (for she was only nineteen) a youngish man. He was a foreigner who lived in Russia as the head of a large commercial undertaking and had grown very rich. It took nothing less than a world war and the overthrow of a great despotism to impoverish him. He fell in love with his young and severe cousin and asked her to be his wife. Her parents put no pressure on her, but she understood their wishes. Behind all her moral ideals she felt the attraction of the fulfilment of a wishful phantasy of helping her father and rescuing him from his necessitous state. She calculated that her cousin would give her father financial support so long as he carried on his business and pension him when he finally gave it up, and that he would provide her sisters with dowries and *trousseaux* so that they could get married. And she fell in love with him, married him soon afterwards and followed him to Russia.

Except for a few occurrences which were not entirely understandable at first sight and whose significance only became evident in retrospect, everything went very well in the marriage. She grew into an affectionate wife, sexually satisfied, and a providential support to her family. Only one thing was wanting: she was childless. She was now 27 years old and in the eighth year of her marriage. She lived in Germany, and after overcoming every kind of hesitation she went for a consultation to a German gynaecologist. With the usual thoughtlessness of a specialist, he assured her of recovery if she underwent a small operation. She agreed, and on the eve of the operation discussed the matter with her husband. It was the hour of twilight and she was about to turn on the lights when her husband asked her not to: he had something to say to her and he would prefer to be in darkness. He told her to countermand the operation, as the blame for their childlessness was his. During a medical congress two years earlier he had learnt that certain illnesses can deprive a man of the capacity to procreate children. An examination had shown that such was the case with him. After this revelation the operation was abandoned. She herself suffered from a temporary collapse, which she vainly sought to disguise. She had only been able to love him as a substitute father, and she had now learnt that he never could be a father. Three paths were open to her, all equally impassable: unfaithfulness, renunciation of her wish for a child, or separation from her husband. The last of them was excluded for the best practical reasons and the middle one for the strongest unconscious ones, which you can easily guess: her whole childhood had been dominated by the thrice disappointed wish to get a child from her father. There remained one other way out, which is what interests us in her case. She fell seriously ill of a neurosis. For a time she put up a defence against various temptations with the help of an anxiety neurosis, but later her symptoms changed into severe obsessional acts. She spent some time in institutions and eventually, after her illness had lasted for ten years, came to me. Her most striking symptom was that when she was in bed she used to fasten [*anstecken* = bring into contact] her sheets to the blankets with safety-pins. In this way she was revealing the secret of her husband's contagion [*Ansteckung*], to which her childlessness was due.

On one occasion, when she was perhaps 40 years old, the patient told me an episode dating back to the time when her depression was beginning, before the outbreak of her obsessional neurosis. To divert her mind, her husband had taken her with him on a business trip to Paris. The couple were sitting with a business friend of her husband's in the hall of their hotel when they became aware of some kind of stir and movement. She asked one of the hotel servants what was happening and was told that Monsieur le Professeur had arrived for consultations in his little room near the hotel entrance. Monsieur le Professeur, it appeared, was a famous fortune-teller; he asked no questions, but got his clients to press down a hand into a dish full of sand and foretold the future by studying the imprint. My patient declared that she would go in and have her fortune told. Her husband dissuaded her, saying it was nonsense. But after he had gone off with his business friend she took off her wedding-ring and slipped into the fortune-teller's cabinet. He made a long study of the imprint of her hand and then spoke as follows: 'In the near future you will have to go through some severe struggles, but all will turn out well. You will get married and have two children by the

Psycho-Analysis And Telepathy

time you are 32.' In telling this story she gave every sign of being greatly impressed by it without understanding it. My comment that it was nevertheless unfortunate that the date laid down by the prophecy had already gone by some eight years made no impression on her. I reflected that perhaps she was admiring the confident boldness of the prophecy - like the faithful disciple of the long-sighted Rabbi.

Unluckily my memory, which is usually so trustworthy, is not certain whether the first part of the prophecy ran: 'All will turn out well. You will get married.' Or whether it was: 'You will become happy.' My attention was focused too completely on my sharp impression of the final phrase with its striking details. But actually the first remarks, about struggles that will have a happy ending, are among the vague expressions that figure in all prophecies - even in those that can be purchased ready-made. The contrast afforded by the two numbers specified in the final phrase is all the more remarkable. Nevertheless, it would certainly have been of interest to know whether the Professor really spoke of her *marriage*. It is true that she had taken off her wedding-ring and, at the age of 27, had looked very youthful and might easily have been taken for an unmarried girl. But, on the other hand, it would not have needed any great refinement of observation to discover the trace of the ring on her finger.

Let us restrict ourselves to the problem contained in the last phrase, which promised her two children at the age of 32. These details seem quite arbitrary and inexplicable. Even the most credulous person would scarcely undertake to deduce them from an interpretation of the lines on a hand. They would have received an indisputable justification if the future had confirmed them. But this was not the case. She was now forty years old and had no children. What, then, were the source and meaning of these numbers? The patient herself had no notion. The obvious thing would be to dismiss the question entirely and to consign it to the rubbish heap among so many other meaningless and ostensibly occult messages. That would be delightful: the simplest solution and a greatly desirable relief. But unluckily I must add that it was possible - and precisely by the help of analysis - to find an explanation of the two numbers and one which, once again, was completely satisfactory and arose, almost as a matter of course, out of the actual situation.

For the two numbers fitted in perfectly with the life-story of - our patient's *mother*. She had not married till she was thirty and it was in her thirty-second year that (unlike most women and to make up, as it were, for her dilatoriness) she gave birth to two children. So it is easy to translate the prophecy: 'There's no need to worry about your present childlessness. There's nothing in that. You can still follow the example of your mother, who was not even married at your age and nevertheless had two children by the time she was thirty-two.' The prophecy promised her the fulfilment of the identification with her mother which had been the secret of her childhood, and it was spoken through the mouth of a fortune-teller who was in ignorance of all her personal affairs and was busy examining an imprint in the sand. And we may add, as the precondition of this wish-fulfilment (unconscious as it was in every sense): 'You will be set free from your useless husband by his death, or you will find strength to separate from him.' The first alternative would fit in better with the nature of an obsessional neurosis, while the second is suggested by the struggles which, according to the prophecy, she was successfully to overcome.

As you will observe, the part played by analytic interpretation is even more important in this example than in the last one. Analysis may actually be said to have created the occult fact. Accordingly, this example, too, would seem to offer positively conclusive evidence of its being possible to transfer an unconscious wish and the thoughts and knowledge relating to it. I can see only one way of evading the conclusiveness of this last case and you may be sure that I shall not conceal it. It is possible that in the course of the twelve or thirteen years that elapsed between the prophecy and the account of it given during the treatment the patient may have formed a paramnesia: the Professor may have uttered some general and colourless consolation - which would be nothing to wonder at - and the patient may have gradually inserted the significant numbers out of her unconscious. If so, we should have avoided the fact which threatened us with such momentous consequences. We will gladly identify ourselves with the sceptics who will only attach value to a report of this kind if it is made immediately after the event - and even then, perhaps, not without hesitation. I remember that after I was appointed to a professorship I had an audience with the Minister to express my thanks. As I was on my way home from this audience I caught myself in the act of trying to falsify the words that had passed between us and I was never able to recapture correctly the actual conversation. I must leave it to you to decide whether the explanation I have suggested is tenable. I can neither prove nor disprove it. Thus, this second observation, though in itself more impressive than the first, is not equally free from doubt.

The two cases that I have reported to you are both concerned with unfulfilled prophecies. Observations of this kind, in my opinion, can provide the best material on the question of thought-transference, and I should like to encourage you to collect similar ones. I had also intended to bring you an example based on material of another kind - a case in which a patient of a special sort talked during one session of things which touched in the most remarkable way on an experience which I had had myself immediately before. But I can now give you visible proof of the fact that I discuss the subject of occultism under the pressure of the greatest resistance. When, while I was at Gastein, I looked out the notes which I had put together and brought with me for the purpose of this paper, the sheet on which I had noted down this last observation was not there, but in its place I found another sheet of indifferent memoranda on quite another topic, which I had brought with me by mistake. Nothing can be done against such a clear resistance. I must ask you to excuse me for omitting this case, for I cannot make the loss good from memory.

I will instead add a few remarks about someone who is very well known in Vienna, a graphologist, Rafael Schermann, who has a reputation for the most astonishing performances. He is said to be able not merely to read a person's character from a specimen of his handwriting, but also to describe his appearance and to add predictions about him which later come true. Incidentally, many of these remarkable achievements are based on his own stories. A friend of mine once, without my previous knowledge, made the experiment of getting him to allow his imagination to play over a specimen of my writing. All that he produced was that the writing was that of an old gentleman (which it was easy to guess), with whom it was hard to live since he was an intolerable tyrant in his home. Those who share my house would hardly confirm this. But, as we know, the field of the occult is subject to the convenient principle that negative cases prove nothing. I have made no direct observations on Schermann, but through a patient of mine I have been in contact with him without his knowing it. I will tell you about it.

A few years ago a young man came to me who made a particularly sympathetic impression on me, so that I gave him preference over a number of others. It appeared that he was involved with one of the best known *demi-mondaines* and that he wanted to get free from her, because the relationship deprived him of all independence of action, but was unable to do so. I succeeded in setting him free and at the same time I obtained full insight into his compulsion. Not many months ago he contracted a normal and respectable marriage. The analysis soon showed that the compulsion against which he was struggling was not a tie with the *demi-mondaine* but with a married lady in his own circle with whom he had had a *liason* from his earliest youth. The *demi-mondaine* served merely as a whipping-boy on whom he could satisfy all the feelings of revenge and jealousy which really applied to the other lady. On a model that is familiar to us, he had made use of displacement onto a fresh object in order to escape the inhibition brought about by his ambivalence.

It was his habit to inflict the most refined torment on the *demi-mondaine*, who had fallen in love with him in an almost unselfish fashion. But when she could no longer conceal her sufferings, he in turn passed over on to her the affection he had felt for the woman he had loved since his youth; he made her presents and propitiated her, and the cycle started on its course once more. When finally, under the influence of the treatment, he broke with her, it became clear what it was that he was trying to achieve by his behaviour to this substitute for his early love: revenge for an attempt at suicide of his own when his love had rejected his advances. After the attempted suicide he had at last succeeded in overcoming her reluctance. During this period of the treatment he used to visit the celebrated Schermann. And the latter, on the basis of specimens of the *demi-mondaine's* handwriting, repeatedly told him by way of interpretation that she was at her last gasp, was at the point of suicide and would quite certainly kill herself. This, however, she did not do, but shook off her human weakness, and recalled the principles of her profession and her duties to her official friend. I saw clearly that the miracle-man had merely revealed to my patient his own intimate wish.

After disposing of this spurious figure, my patient set about seriously the task of freeing himself from his real bond. I detected from his dreams a plan that he was forming by means of which he would be able to escape from his relation with his early love without causing her too much mortification or material damage. She had a daughter, who was very fond of the young friend of the family and ostensibly knew nothing of the secret part he played. He now proposed to marry this girl. Soon afterwards the scheme became conscious, and the man took the first steps towards putting it into effect. I supported his intentions, since it offered what was a possible way out of his difficult situation even though an irregular one. But presently there came a dream which showed hostility to the girl; and now once more he consulted Schermann, who reported that the girl was childish and neurotic and should not be married. This time the great observer of human nature was right. The girl, who was by now regarded as the man's *fiancée*, behaved in a more and more contradictory manner, and it was decided that she should be analysed. As a result of the analysis the scheme for the marriage was abandoned. The girl had a complete unconscious knowledge of the relations between her mother and her *fiancé*, and was only attached to him on account of her Oedipus complex.

At about this time our analysis broke off. The patient was free and capable of going his own way in the future. He chose as his wife a respectable girl outside his family circle - a girl on whom Schermann has passed a favourable judgement. Let us hope that this time he will be right once more.

You will have grasped the sense in which I am inclined to interpret these experiences of mine with Schermann. You will see that all my material touches only on the single point of thought-transference. I have nothing to say about all the other miracles that are claimed by occultism. My own life, as I have already openly admitted, has been particularly poor in an occult sense. Perhaps the problem of thought-transference may seem very trivial to you in comparison with the great magical world of the occult. But consider what a momentous step beyond what we have hitherto believed would be involved in this hypothesis alone. What the custodian of Saint-Denis used to add to his account of the saint's martyrdom remains true. Saint-Denis is said, after his head was cut off, to have picked it up and to have walked quite a distance with it under his arm. But the custodian used to remark: '*Dans des cas pareils, ce n'est que le premier pas qui coûte.*' The rest is easy.

DREAMS AND TELEPATHY
(1922)

Intentionally left blank

DREAMS AND TELEPATHY

At the present time, when such great interest is felt in what are called 'occult' phenomena, very definite anticipations will doubtless be aroused by the announcement of a paper with this title. I will therefore hasten to explain that there is no ground for any such anticipations. You will learn nothing from this paper of mine about the enigma of telepathy; indeed, you will not even gather whether I believe in the existence of 'telepathy' or not. On this occasion I have set myself the very modest task of examining the relation of the telepathic occurrences in question, whatever their origin may be, to dreams, or more exactly, to our theory of dreams. You will know that the connection between dreams and telepathy is commonly held to be a very intimate one; I shall put forward the view that the two have little to do with each other, and that if the existence of telepathic dreams were to be established there would be no need to alter our conception of dreams in any way.

The material on which the present communication is based is very slight. In the first place, I must express my regret that I could make no use of my own dreams, as I did when I wrote my *Interpretation of Dreams* (1900a). But I have never had a 'telepathic' dream. Not that I have been without dreams of the kind that convey an impression that a certain definite event is happening at some distant place, leaving it to the dreamer to decide whether the event is happening at that moment or will do so at some later time. In waking life, too, I have often become aware of presentiments of distant events. But these hints, foretellings and premonitions have none of them 'come true', as we say; there proved to be no external reality corresponding to them, and they had therefore to be regarded as purely subjective anticipations.

For example, I once dreamt during the war that one of my sons then serving at the front had been killed. This was not directly stated in the dream, but was expressed in an unmistakable manner, by means of the well-known death-symbolism of which an account was first given by Stekel. (We must not omit to fulfil the duty, often felt to be inconvenient, of making literary acknowledgements.) I saw the young soldier standing on a landing-stage, between land and water, as it were; he looked to me very pale. I spoke to him but he did not answer. There were other unmistakable indications. He was not wearing military uniform, but a ski-ing costume that he had worn when a serious ski-ing accident had happened to him several years before the war. He stood on something like a footstool with a cupboard in front of him; a situation always closely associated in my mind with the idea of 'falling', through a memory of my own childhood. As a child of little more than two years old I had myself climbed on a footstool like this to get something off the top of a cupboard - probably something good to eat - and I fell down and gave myself an injury, of which I can even now show the scar. My son, however, whom the dream pronounced to be dead, came home from the war unscathed.

Only a short time ago, I had another dream bearing ill-tidings; it was, I think, just before I decided to put together these few remarks. This time there was not much attempt at disguise. I saw my two nieces who live in England. They were dressed in black and said to me, 'We buried her on Thursday.' I knew the reference was to the death of their mother, now eighty-seven years of age, the widow of my eldest brother.

A time of disagreeable anticipation followed; there would of course be nothing surprising in such an old lady suddenly passing away, yet it would be very unpleasant for the dream to coincide exactly with the occurrence. The next letter from England, however, dissipated this fear. For the benefit of those who are concerned for the wish-fulfilment theory of dreams I may interpolate a reassurance by saying that there was no difficulty in detecting by analysis the unconscious motives that might be presumed to exist in these death-dreams just as in others.

I hope you will not object that what I have just related is valueless because negative experiences prove as little here as they do in less occult matters. I am well aware of that and have not adduced these instances with any intention whatever of proving anything or of surreptitiously influencing you in any particular direction. My sole purpose was to explain the paucity of my material.

Another fact certainly seems to me of more significance, namely, that during some twenty-seven years of work as an analyst I have never been in a position to observe a truly telepathic dream in any of my patients. And yet those patients made up a fair collection of severely neuropathic and 'highly sensitive' natures. Many of them have related to me most remarkable incidents in their earlier life on which they based a belief in mysterious occult influences. Events such as accidents or illnesses of near relatives, in particular the death of a parent, have often enough happened during the treatment and interrupted it; but not on one single occasion did these occurrences, eminently suitable as they were in character, afford me the opportunity of registering a single telepathic dream, although treatment extended over several months or even years. Anyone who cares to may look for an explanation of this fact, which still further restricts the material at my disposal. In any case it will be seen that such an explanation would not affect the subject of this paper.

Nor does it embarrass me to be asked why I have made no use of the abundant store of telepathic dreams that have appeared in the literature of the subject. I should not have had far to seek, since the publications of the English as well as of the American Society for Psychical Research are accessible to me as a member of both societies. In none of these communications is any attempt ever made to subject such dreams to analytic investigation, which would be our first interest in such cases.¹ Moreover, you will soon perceive that for the purposes of this paper one single dream will serve well enough.

My material thus consists simply and solely of two communications which have reached me from correspondents in Germany. The writers are not personally known to me, but they give their names and addresses: I have not the least ground for presuming any intention to mislead on their part.

¹ In two publications by W. Stekel, the author mentioned above (*Der telepathische Traum*, no date, and *Die Sprache des Traumes*, Second Edition, 1922), there are at least attempts to apply the analytic technique to alleged telepathic dreams. The author expresses his belief in the reality of telepathy.

I

With the first of the two I had already been in correspondence; he had been good enough to send me, as many of my readers do, observations of everyday occurrences and the like. He is obviously an educated and highly intelligent man; this time he expressly places his material at my disposal if I care to turn it 'to literary account'.

His letter runs as follows:

'I consider the following dream of sufficient interest for me to hand it on to you as material for your researches.

'I must first state the following facts. My daughter, who is married and lives in Berlin, was expecting her first confinement in the middle of December of this year. I intended to go to Berlin about that time with my (second) wife, my daughter's stepmother. During the night of November 16-17 I dreamt, with a vividness and clearness I have never before experienced, that *my wife, had given birth to twins. I saw the two healthy infants quite plainly with their chubby faces lying in their cot side by side. I did not observe their sex; one with fair hair had distinctly my features and something of my wife's, the other with chestnut-brown hair clearly resembled her with a look of me. I said to my wife, who has red-gold hair, "Probably 'your' child's chestnut hair will also go red later on." My wife gave them the breast. In the dream she had also made some jam in a wash-basin and the two children crawled about on all fours in the basin and licked up the contents.*

'So much for the dream. Four or five times I had half woken from it, asked myself if it were true that we had twins, but did not come to the conclusion with any certainty that it was only a dream. The dream lasted till I woke, and after that it was some little time before I felt quite clear about the true state of affairs. At breakfast I told my wife the dream, which much amused her. She said, "Surely Ilse (my daughter) won't have twins?" I answered, "I should hardly think so, as twins are not the usual thing either in my family or in G.'s" (her husband). On November 18, at ten o'clock in the morning, I received a telegram from my son-in-law, handed in the afternoon before, telling me of the birth of twins, a boy and a girl. The birth thus took place at the time when I was dreaming that my wife had twins. The confinement occurred four weeks earlier than any of us had expected on the basis of my daughter and son in-law's calculations.

'But there is a further circumstance: the next night I dreamt *that my deceased wife, my daughter's own mother, had undertaken the care of forty-eight new-born infants. When the first dozen were being brought in, I protested.* At that point the dream ended.

'My late wife was very fond of children. She often talked about it, saying she would like a whole troop round her, the more the better, and that she would do very well if she had charge of a Kindergarten and would be quite happy so. The noise children make was music to her. From time to time she would invite in a whole troop of children from the streets and regale them with chocolate and cakes in the courtyard of our villa. My daughter must have thought at once of her mother after her confinement, especially because of the surprise of its coming on prematurely, the arrival of twins, and their difference in sex. She knew her mother would have greeted the event with the liveliest joy and sympathy. "Only think what mother would say, if she were with me now!" This thought must undoubtedly have gone through her mind. And then I dream of my dead wife, of whom I very seldom dream, and had neither spoken of nor thought of after the first dream.

'Do you think that the coincidence between dream and event was accidental in both cases? My daughter is much attached to me and was most certainly thinking of me during her labour, particularly because we had often exchanged letters about her mode of living during her pregnancy and I had constantly given her advice.'

It is easy to guess what my answer to this letter was. I was sorry to find that my correspondent's interest in analysis had been so completely killed by his interest in telepathy. I therefore avoided his direct question, and, remarking that the dream contained a good deal besides its connection with the birth of the twins, I asked him to give me any information or ideas that occurred to him which could give me a clue to the meaning of the dream.

Thereupon I received the following second letter which, it must be admitted, did not give me quite all I wanted:

'I have not been able to answer your kind letter of the 24th until to-day. I shall be only too pleased to tell you "without omission or reserve" all the associations that occur to me. Unfortunately there is not much; more would come out in talking.

'Well then - my wife and I do not wish for any more children. We almost never have sexual intercourse; at any rate at the time of the dream there was certainly no "danger". My daughter's confinement, which was expected about the middle of December, was naturally a frequent subject of conversation between us. My daughter had been examined and X-rayed in the summer, and the doctor making the examination was certain that the child would be a boy. My wife said at the time, "I should laugh if it was a girl after all." At the time she also remarked that it would be better if it were an H. rather than a G. (my son-in-law's family name); my daughter is handsomer and has a better figure than my son-in-law, although he has been a naval officer. I have made some study of the question of heredity and am in the habit of looking at babies to see whom they resemble. One more thing. We have a small dog which sits with us at table in the evening to have his food and licks the plates and dishes. All this material appears in the dream.

'I am fond of small children and have often said that I should like to have the bringing up of a child once more, now that I should have so much more understanding, interest and time to devote to it; but with my wife I should not wish it, as she does not possess the necessary qualities for rearing a child judiciously. The dream makes me a present of two children - I did not observe their sex. I see them even at this moment lying in the bed and I recognize the features, the one more "me", the other more my wife, but each with minor traits from the other side. My wife has red-gold hair, but the one child had chestnut (reddish) brown hair. I said, "Oh well, it will go red, too, later on." Both the children crawl round a large wash basin in which my wife has been stirring jam and lick its bottom and sides (dream). The origin of this detail is easily explicable, just as is the dream as a whole. The dream would not be difficult to understand or interpret if it had not coincided with the unexpectedly early arrival of my grandchildren (three weeks too soon), a coincidence of time almost to the hour. (I cannot exactly say when the dream began; my grandchildren were born at nine p. m. and a quarter past; I went to bed at about eleven and had my dream during the course of the night.) Our knowledge too that the child would be a boy adds to the difficulty, though possibly the doubt whether this had been fully established might account for the appearance of twins in the dream. All the same, there remains the coincidence of the dream with the unexpected and premature appearance of my daughter's twins.

'It is not the first time that distant events have become known to me before I received the actual news. To give one instance among many. In October I had a visit from my three brothers. We had not all been together for thirty years, except for quite a short time, once at my father's funeral and once at my mother's. Both deaths were expected, and I had had no 'presentiments' in either case. But about twenty-five years ago my youngest brother died quite suddenly and unexpectedly when he was ten. As the postman handed me the postcard with the news of his death, before I had glanced at it, the thought came to me at once, "It is to say that your brother is dead." He was the only one left at home, a strong healthy lad, while we four elder brothers were already fully fledged and had left our parents' house. At the time of my brothers' visit the talk by chance came round to this experience of mine, and, as if at the word of command, all three brothers came out with the declaration that exactly the same thing had happened to them. Whether it happened in exactly the same manner I cannot say; at all events each one said that he had felt perfectly certain of the death just before the quite unexpected news had arrived. We are all from the mother's side of a sensitive disposition, though tall, strong men, but not one of us is in the least inclined towards spiritualism or occultism; on the contrary, we disclaim adherence to either. My brothers are all three University men, two are schoolmasters, one a surveyor, all rather pedants than visionaries. - That is all I can tell you in regard to the dream. If you can turn it to literary account, I am delighted to place it at your disposal.'

I am afraid that you may behave like the writer of these two letters. You, too, will be primarily interested in the question whether this dream can really be regarded as a telepathic notification of the unexpected birth of the twin children, and you will not be disposed to submit this dream to analysis like any other. I foresee that it will always be so when psycho-analysis and occultism encounter each other. The former has, so to speak, all our mental instincts against it; the latter is met half-way by powerful and mysterious sympathies. I am not, however, going to take up the position that I am nothing but a psycho-analyst, that the problems of occultism do not concern me: you would rightly judge that to be only an evasion of a problem. On the contrary, I may say that it would be a great satisfaction to me if I could convince myself and others on unimpeachable evidence of the existence of telepathic processes, but I also consider that the information provided about this dream is altogether inadequate to justify any such pronouncement. You will observe that it does not once occur to this intelligent man, deeply interested as he is in the problem of his dream, to tell us when he had last seen his daughter or what news he had lately had from her. He writes in the first letter that the birth was a month too soon; in the second, however, the month has become three weeks only, and in neither are we told whether the birth was really premature, or whether, as so often happens, those concerned were out in their reckoning. But we should have to consider these and other details of the occurrence if we are to weigh the probability of the dreamer having made unconscious estimates and guesses. I felt too that it would be of no use even if I succeeded in getting answers to such questions. In the course of arriving at the information new doubts would constantly arise, which could only be set at rest if one had the man in front of one and could revive all the relevant memories which he had perhaps dismissed as unessential. He is certainly right in what he says at the beginning of his second letter that more would have come out in talking.

Consider another and similar case, in which the disturbing interest of occultism has no part. You must often have been in a position to compare the anamnesis and the information about the illness given during the first session by any neurotic with what you have gained from him after some months of psycho-analysis. Apart from inevitable abbreviations, how many essentials were left out or suppressed, how many connections were displaced - in fact, how much that was incorrect or untrue was told you on that first occasion! You will not call me hyper-critical if I refuse in the circumstances to make any pronouncement whether the dream in question is a telepathic event or a particularly subtle achievement on the part of the dreamer's unconscious or whether it is simply to be taken as a striking coincidence. Our curiosity must be satisfied with the hope of some later occasion on which it may be possible to make a detailed oral examination of the dreamer. But you cannot say that this outcome of our investigation has disappointed you, for I prepared you for it; I said you would hear nothing which would throw any light on the problem of telepathy.

If we now pass on to the analytic treatment of this dream, we are obliged once more to express dissatisfaction. The thoughts that the dreamer associates with the manifest content of the dream are again insufficient; they do not enable us to make any analysis of the dream. For instance, the dream goes into great detail over the likeness of the children to the parents, discusses the colour of their hair and the probable change of colour at a later age, and as an explanation of these elaborate details we only have the dry piece of information from the dreamer that he has always been interested in questions of likeness and heredity. We are accustomed to expect rather more material than this! But at *one* point the dream does admit of an analytic interpretation, and precisely at this point analysis, which has otherwise no connection with occultism, comes to the aid of telepathy in a remarkable way. It is only on account of this single point that I am asking for your attention to this dream at all.

Correctly speaking, this dream has no right whatever to be called 'telepathic'. It did not inform the dreamer of anything which (outside his normal knowledge) was taking place elsewhere. What the dream did relate was something quite different from the event reported in the telegram received on the second day after the night of the dream. The dream and the actual occurrence diverge at a particularly important point; but they agree, apart from the coincidence of time, in another very interesting element. In the dream the dreamer's *wife* had twins. The occurrence, however, was that his *daughter* had given birth to twins in her distant home. The dreamer did not overlook this difference; he did not seem to know any way of getting over it and, as according to his own account he had no leaning towards the occult, he only asked quite tentatively whether the coincidence between dream and occurrence on the point of the twin-birth could be more than an accident. The psycho-analytic interpretation of dreams, however, does away with this difference between the dream and the event, and gives both the same content. If we consult the associative material to this dream, it shows, in spite of its sparseness, that an intimate bond of feeling existed between the father and daughter, a bond of feeling which is so usual and so natural that we ought to cease to be ashamed of it, one that in daily life merely finds expression as a tender interest and is only pushed to its logical conclusion in dreams. The father knew that his daughter clung to him, he was convinced that she often thought of him during her labour. In his heart I think he grudged her to his son-in-law, to whom in one letter he makes a few disparaging references. On the occasion of her confinement (whether expected or communicated by telepathy) the unconscious wish became active in the repressed part of his mind: 'she ought to be my (second) wife instead'; it was this wish that had distorted the dream-thoughts and was the cause of the difference between the manifest content of the dream and the event. We are entitled to replace the second wife in the dream by the daughter. If we possessed more associations to the dream, we could undoubtedly verify and deepen this interpretation.

And now I have reached the point I wish to put before you. We have endeavoured to maintain the strictest impartiality and have allowed two conceptions of the dream to rank as equally probable and equally unproved. According to the first the dream is a reaction to a telepathic message: 'your daughter has just brought twins into the world.' According to the second an unconscious process of thought underlies the dream, which may be reproduced somewhat as follows: 'To-day is the day the confinement should take place if the young people in Berlin are really out in their reckoning by a month, as I suspect. And if my (first) wife were still alive, she certainly would not be content with one grandchild. To please her there would have to be at least twins!' If this second view is right, no new problems arise. It is simply a dream like any other. The (preconscious) dream-thoughts as outlined above are reinforced by the (unconscious) wish that no other than the daughter should be the dreamer's second wife, and thus the manifest dream as described to us arises.

If you prefer to assume that a telepathic message about the daughter's confinement reached the sleeper, further questions arise of the relation of a message such as this to a dream and of its influence on the formation of dreams. The answer is not far to seek and is quite unambiguous. A telepathic message will be treated as a portion of the material that goes to the formation of a dream, like any other external or internal stimulus, like a disturbing noise in the street or an insistent organic sensation in the sleeper's own body. In our example it is evident how the message, with the help of a lurking repressed wish, became remodelled into a wish-fulfilment; it is unfortunately less easy to show that it combined with other material that had become active at the same time and was blended into a dream. Telepathic messages - if we are justified in recognizing their existence - can thus make no alteration in the process of forming a dream; telepathy has nothing to do with the nature of dreams. And in order to avoid the impression that I am trying to conceal a vague notion behind abstract and fine-sounding words, I am willing to repeat: the essential nature of dreams consists in the peculiar process of 'dream-work' which, with the help of an unconscious wish, carries the preconscious thoughts (day's residues) over into the manifest content of the dream. The problem of telepathy concerns dreams as little as does the problem of anxiety.

I am hoping that you will grant this, but that you will raise the objection that there are, nevertheless, other telepathic dreams in which there is no difference between the event and the dream, and in which there is nothing else to be found but an undistorted reproduction of the event. I have no knowledge of such dreams from my own experience, but I know they have often been reported. If we assume that we have such an undisguised and unadulterated telepathic dream to deal with, another question arises. Ought we to call such a telepathic experience a 'dream' at all? You will certainly do so as long as you keep to popular usage, in which everything that takes place in mental life during sleep is called a dream. You, too, perhaps say, 'I tossed about in my dream', and still less are you conscious of anything incorrect when you say, 'I shed tears in my dream' or 'I felt apprehensive in my dream'. But you will no doubt notice that in all these cases you are using 'dream' and 'sleep' and 'state of being asleep' interchangeably, as if there were no distinction between them. I think it would be in the interests of scientific accuracy to keep 'dream' and 'state of sleep' more distinctly separate. Why should we provide a counterpart to the confusion evoked by Maeder who, by refusing to distinguish between the dream-work and the latent dream-thoughts, has discovered a new function for dreams? Supposing, then, that we are brought face to face with a pure telepathic 'dream', let us rather call it instead a telepathic experience in a state of sleep. A dream without condensation, distortion, dramatization, above all, without wish-fulfilment, surely does not deserve the name. You will remind me that, if so, there are *other* mental products in sleep to which the right to be called 'dreams' would have to be refused. Actual experiences of the day are sometimes simply repeated in sleep; reproductions of traumatic scenes in 'dreams' have led us only lately to revise the theory of dreams. There are dreams which are to be distinguished from the usual type by certain special qualities, which are, properly speaking, nothing but night-phantasies, not having undergone additions or alterations of any kind and being in all other ways similar to the familiar day-dreams. It would be awkward, no doubt, to exclude these structures from the domain of 'dreams'. But still they all come from within, are products of our mental life, whereas the very conception of the purely 'telepathic dream' lies in its being a perception of something external, in relation to which the mind remains passive and receptive.

II

The second case which I shall bring before your notice in fact follows along other lines. This is not a telepathic dream, but a dream that has recurred from childhood onwards, in a person who has had many telepathic experiences. Her letter, which I reproduce here, contains some remarkable things, about which we cannot form any judgement. A part of it is of interest in connection with the problem of the relation of telepathy to dreams.

(1) ' . . . My doctor, Herr Dr. N., advises me to give you an account of a dream that has pursued me for some thirty or thirty-two years. I am following his advice, and perhaps the dream may possess interest for you in some scientific respect. Since, in your opinion, such dreams are to be traced to an experience of a sexual nature in the first years of my childhood, I relate some reminiscences of childhood. They are experiences whose impression on me still persists and which were of so marked a character as to have determined my religion for me.

'May I beg of you to send me word in what way you explain this dream and whether it is not possible to banish it from my life, for it haunts me like a ghost, and the circumstances that always accompany it - I always fall out of bed, and have inflicted on myself not inconsiderable injuries - make it particularly disagreeable and distressing.'

(2) 'I am thirty-seven years old, very strong and in good physical health, but in childhood I had, besides measles and scarlet fever, an attack of nephritis. Furthermore, in my fifth year I had a very severe inflammation of the eyes, which left double vision. The images are at an angle to each other and their outline is blurred, as the scars from the ulcers affect clearness of vision. In the specialist's opinion there is nothing more to be done to the eyes and no chance of improvement. The left side of my face is drawn up from having screwed up my left eye to see better. By dint of practice and determination I can do the finest needlework; and, similarly, when a six-year old child, I broke myself of squinting by practising in front of a looking-glass, so that now there is no external sign of the defect in vision.

'From my very earliest years I was always solitary. I kept apart from other children, and had visions (clairvoyance and clairsaudience). I was not able to distinguish these from reality, and in consequence often found myself in conflict with other people in embarrassing positions, with the result that I have become a very reserved and shy person. Since as a quite small child I already knew far more than I could have learnt, I simply did not understand children of my own age. I am myself the eldest of a family of twelve.

'From six to ten years old I attended the parish school and up to sixteen the high-school of the Ursuline Nuns in B--. At ten I had taken in as much French in four weeks, in eight lessons, as other children learn in two years. I had only to say it over. It was just as if I had already learnt it and only forgotten it. I have never had any need to learn French, in contradistinction to English, which gave me no trouble, certainly, but which was not known to me beforehand. The same thing happened to me with Latin as with French and I have never properly learnt it, only knowing it from Church Latin, which is, however, quite familiar to me. If I read a French book to-day, then I immediately begin thinking in French, whereas this never happens to me with English, although I have more command of English. My parents are peasant people (who for generations have never spoken any languages except German and Polish.

'*Visions.* - Sometimes reality vanishes for some moments and I see something quite different. In my house, for example, I often see an old married couple and a child; and the house is then differently furnished. In the sanatorium a friend once came into my room at about four in the morning; I was awake, had the lamp burning, and was sitting at my table reading, as I suffer much from sleeplessness. This apparition of her always means a trying time for me - as it did on this occasion.

'In 1914 my brother was on active service; I was not with my parents in B-- but in Ch--. It was ten a. m. on August 22 when I heard my brother's voice calling, "Mother! Mother!" It came again ten minutes later, but I saw nothing. On August 24 I came home, found my mother greatly depressed, and in answer to my questions she said that she had had a message from the boy on August 22. She had been in the garden in the morning, when she had heard him call, "Mother! Mother!" I comforted her and said nothing about myself. Three weeks after there came a card from my brother, written on August 22 between nine and ten in the morning; shortly after that he died.

'On September 27, 1921, while in the sanatorium, I received a message of some kind. There were violent knockings two or three times repeated on the bed of the patient who shared my room. We were both awake; I asked if she had knocked; she had not even heard anything. Eight weeks later I heard that one of my friends had died in the night of September 26-7.

'Now something which is regarded as a hallucination - a matter of opinion! I have a friend who married a widower with five children; I got to know the husband only through my friend. Nearly every time that I have been to see her, I have seen a lady going in and out of the house. It was natural to suppose that this was the husband's first wife. I asked at some convenient opportunity for a portrait of her, but could not identify the apparition with the photograph. Seven years later I saw a picture with the features of the lady, belonging to one of the children. It was the first wife after all. In the picture she looked in much better health: she had just been through a feeding-up treatment and that alters the appearance of a consumptive patient. These are only a few examples out of many.

'The dream. - I saw a tongue of land surrounded by water. The waves were being driven forward and then back by the breakers. On this piece of land stood a palm-tree, bent somewhat towards the water. A woman had her arm wound round the stem of the palm and was bending low towards the water, where a man was trying to reach the shore. At last she lay down on the ground, held tightly to the palm-tree with her left hand and stretched out her right hand as far as she could towards the man in the water, but without reaching him. At that point I would fall out of bed and wake. I was about fifteen or sixteen years old when I realized that this woman was myself, and from that time I not only experienced all the woman's apprehensions on behalf of the man but sometimes stood there as a third person looking on at the scene without taking part in it. I dreamed this dream too in separate scenes. As an interest in men awoke in me (at eighteen to twenty years old), I tried to see the man's face; but this was never possible. The foam hid everything but his neck and the back of his head. I have twice been engaged to be married, but judging by his head and build he was neither of the two men I was engaged to. - Once, when I was lying in the sanatorium under the influence of paraldehyde, I saw the man's face, which I now always see in this dream. It was that of the doctor under whose care I was. I liked him as a doctor, but I was not drawn to him in any other way.

'Memories. Six to nine months old. - I was in a perambulator. On my right were two horses; one, a brown, was looking at me very intently and expressively. This was my most vivid experience; I had the feeling that it was a human being.

'*One year old.* - Father and I in the town-park, where a park-keeper was putting a little bird into my hand. Its eyes looked back into mine. I felt "That is a creature like yourself".

'*Animals being slaughtered.* - When I heard the pigs squealing I always called for help and cried out "You are killing a person" (four years old). I always refused to eat meat. Pork always makes me vomit. It was not till the war that I came to eat meat, and only unwillingly; now I am learning to do without it again.

'*Five years old.* - My mother was confined and I heard her cry out. I had the feeling, "There is a human being or an animal in the greatest distress", just as I had over the pig-killing.

'I was quite indifferent as a child to sexual matters; at ten years old I had as yet no conception of offences against chastity. Menstruation came on at the age of twelve. The woman first awakened in me at six-and-twenty, after I had given life to a child; up to that time (six months) I constantly had violent vomiting after intercourse. This also came on whenever I was at all oppressed in mood.

'I have extraordinarily keen powers of observation, and quite exceptionally sharp hearing, also a very keen sense of smell. With my eyes bandaged I can pick out by smell people I know from among a number of others.

'I do not regard my abnormal powers of sight and hearing as pathological, but ascribe them to finer perceptions and greater quickness of thought; but I have only spoken of it to my pastor and to Dr.-- (very unwillingly to the latter, as I was afraid he would tell me that what I regarded as *plus*-qualities were *minus*-qualities, and also because from being misunderstood in childhood I am very reserved and shy).'

The dream which the writer of the letter asks us to interpret is not hard to understand. It is a dream of rescuing from water, a typical birth-dream. The language of symbolism, as you are aware, knows no grammar; it is an extreme case of a language of infinitives, and even the active and passive are represented by one and the same image. If in a dream a woman pulls (or tries to pull) a man out of the water, that may mean that she wants to be his mother (takes him for her son as Pharaoh's daughter did with Moses). Or it may mean that she wants him to make her into a mother: she wants to have a son by him, who, as a likeness of him, can be his equivalent. The tree-trunk to which the woman was clinging is easily recognized as a phallic symbol, even though it is not standing straight up, but inclined towards the surface of the water - in the dream the word is 'bent'. The onrush and recoil of the breakers brought to the mind of another dreamer who was relating a similar dream a comparison with the intermittent pains of labour; and when, knowing that she had not yet borne a child, I asked her how she knew of this characteristic of labour, she said that she imagined labour as a kind of colic - a quite unimpeachable description physiologically. She gave the association '*The Waves of the Sea and of Love*'. How our present dreamer at so early an age can have arrived at the finer details of symbolism - tongue of land, palm-tree - I am naturally unable to say. We must not, moreover, overlook the fact that, when people assert that they have for years been pursued by the same dream, it often turns out that the manifest content is not quite the same. Only the kernel of the dream has recurred each time; the details of the content are changed or additions are made to them.

At the end of this dream, which is clearly charged with anxiety, the dreamer falls out of bed. This is a fresh representation of childbirth. Analytic investigation of the fear of heights, of the dread of an impulse to throw oneself out of the window, has doubtless led you all to the same conclusion.

Who then is the man, by whom the dreamer wishes to have a child, or of whose likeness she would like to be the mother? She often tried to see his face, but the dream never allowed her to; the man had to remain *incognito*. We know from countless analyses what this concealment means, and the conclusion we should base on analogy is verified by another statement of the dreamer's. Under the influence of paraldehyde she once recognized the face of the man in the dream as that of the hospital physician who was treating her, and who meant nothing more to her conscious emotional life. The original thus never divulged its identity, but this impression of it in 'transference' establishes the conclusion that earlier it must always have been her father. Ferenczi is perfectly right in pointing out that these 'dreams of the unsuspecting' are valuable sources of information, as confirming the conjectures of analysis. Our dreamer was the eldest of twelve children; how often must she have suffered the pangs of jealousy and disappointment when it was not she but her mother who obtained from her father the child she longed for!

Our dreamer quite correctly supposed that her first memories of childhood would be of value in the interpretation of her early and recurrent dream. In the first scene, before she was one year old, as she was sitting in her perambulator she saw two horses beside her, one looking at her. This she described as her most vivid experience; she had the feeling that it was a human being. This was a feeling which we can understand only if we assume that the two horses represented, in this case as so often, a married couple, father and mother. It was, as it were, a flash of infantile totemism. If we could, we should ask the writer whether the *brown* horse who looked at her so humanly could not be recognized by its colouring as her father. The second recollection was associatively connected with the first through the same 'understanding' gaze. Taking the little bird in her hand, however, reminds the analyst, who has prejudices of his own, of a feature in the dream in which the woman's hand was in contact with another phallic symbol.

The next two memories belong together; they make still slighter demands on the interpreter. The mother crying out during her confinement reminded the daughter directly of the pigs squealing when they were being killed and put her into the same frenzy of pity. But we may also conjecture that this was a violent reaction against an angry death-wish directed at the mother.

With these indications of tenderness for her father, of contact with his genitals, and of death-wishes against her mother, the outline of the female Oedipus complex is sketched in. Her long retention of her ignorance of sexual matters, and her frigidity at a later period bear out these suppositions. The writer of the letter became potentially - and at times no doubt actually - a hysterical neurotic. The forces of life have, for her own happiness, carried her along with them. They have awakened in her the sexual feelings of a woman and brought her the joys of motherhood, and the capacity to work. But a portion of her libido still clings to its points of fixation in childhood; she still dreams the dream that throws her out of bed and punishes her for her incestuous object-choice by 'not inconsiderable injuries'.

And now an explanation, given in writing by a doctor who was a stranger to her, was expected to effect what all the most important experiences of her later life had failed to do! Probably a regular analysis continued for a considerable time would have succeeded in this. As things were, I was obliged to content myself with writing to her that I was convinced she was suffering from the after-effects of a strong emotional tie binding her to her father and from a corresponding identification with her mother, but that I did not myself expect that this explanation would help her. Spontaneous cures of neurosis usually leave scars behind, and these become painful again from time to time. We are very proud of our art if we achieve a cure through psycho-analysis, yet here too we cannot always prevent the formation of a painful scar as an outcome.

The little series of reminiscences must engage our attention for a while longer. I have stated elsewhere that such scenes of childhood are 'screen memories' selected at a later period, put together, and not infrequently falsified in the process. This subsequent remodelling serves a purpose that is sometimes easy to guess. In our case one can almost hear the writer's ego glorifying or soothing itself by means of this series of recollections. 'I was from infancy a particularly noble and compassionate creature. I learnt quite early that animals have souls as we have, and could not endure cruelty to animals. The sins of the flesh were far from me and I preserved my chastity till late in life.' With declarations such as these she was loudly contradicting the inferences that we have to make about her early childhood on the basis of our analytical experience, namely, that she had an abundance of premature sexual impulses and violent feelings of hatred for her mother and her younger brothers and sisters. (Besides the genital significance I have just assigned to it, the little bird may also be a symbol of a child, like all small animals; her recollection thus accentuated very insistently the fact that this small creature had the same right to exist as she herself.) Hence the short series of recollections furnishes a very nice example of a mental structure with a twofold aspect. Viewed superficially, we may find in it the expression of an abstract idea, here, as usually, with an ethical reference. In Silberer's nomenclature the structure has an *anagogic* content. On deeper investigation it reveals itself as a chain of phenomena belonging to the region of the repressed life of the instincts - it displays its *psycho-analytic* content. As you know, Silberer, who was among the first to issue a warning to us not to lose sight of the nobler side of the human soul, has put forward the view that all or nearly all dreams permit such a twofold interpretation, a purer, anagogic one beside the ignoble, psycho-analytic one. This is, however, unfortunately not so. On the contrary, an over-interpretation of this kind is rarely possible. To my knowledge no valid example of such a dream-analysis with a double meaning has been published up to the present time. But observations of this kind can often be made upon the series of associations that our patients produce during analytic treatment. On the one hand the successive ideas are linked by a line of association which is plain to the eye, while on the other hand you become aware of an underlying theme which is kept secret but which at the same time plays a part in all these ideas. The contrast between the two themes that dominate the same series of ideas is not always one between the lofty anagogic and the low psycho-analytic, but one rather between offensive and respectable or indifferent ideas - a fact that easily explains why such a chain of associations with a twofold determination arises. In our present example it is of course not accidental that the anagogic and the psycho-analytic interpretations stood in such a sharp contrast to each other; both related to the same material, and the later trend was no other than that of the reaction-formations which had been erected against the disowned instinctual impulses.

But why do we look for a psycho-analytic interpretation at all instead of contenting ourselves with the more accessible anagogic one? The answer to this is linked up with many other problems - with the existence in general of neurosis and the explanations it inevitably demands - with the fact that virtue does not reward a man with as much joy and strength in life as one would expect, as though it brought with it too much of its origin (our dreamer, too, had not been well rewarded for her virtue), and with other things which I need not discuss before this audience.

So far, however, we have completely neglected the question of telepathy, the other point of interest for us in this case; it is time to return to it. In a sense we have here an easier task than in the case of Herr H. With a person who so easily and so early in life lost touch with reality and replaced it by the world of phantasy, the temptation is irresistible to connect her telepathic experiences and 'visions' with her neurosis and to derive them from it, although here too we should not allow ourselves to be deceived as to the cogency of our own arguments. We shall merely be replacing what is unknown and unintelligible by possibilities that are at least comprehensible.

On August 22, 1914, at ten o'clock in the morning, our correspondent experienced a telepathic impression that her brother, who was at the time on active service, was calling, 'Mother! Mother!'; the phenomenon was purely acoustic, it was repeated shortly after, but nothing was seen. Two days later she saw her mother and found her much depressed because the boy had announced himself to her with a repeated call of 'Mother! Mother!' She immediately remembered the same telepathic message, which she had experienced at the same time, and as a matter of fact some weeks later it was established that the young soldier had died on that day at the hour in question.

It cannot be proved, but also cannot be disproved, that instead of this, what happened was the following. Her mother told her one day that her son had sent a telepathic message; whereupon the conviction at once arose in her mind that she had had the same experience at the same time. Such illusions of memory arise in the mind with a compelling force which they draw from real sources; but they turn psychical reality into material reality. The strength of the illusion lies in its being an excellent way of expressing the sister's proneness to identify herself with her mother. 'You are anxious about the boy, but I am really his mother, and his cry was meant for me; I had this telepathic message.' The sister would naturally firmly reject our attempt at explanation and would hold to her belief in the authenticity of her experience. But she could not do otherwise. She would be bound to believe in the reality of the pathological effect so long as the reality of its unconscious premises were unknown to her. Every such delusion derives its strength and its unassailable character from having a source in unconscious psychical reality. I note in passing that it is not incumbent on us here to explain the mother's experience or to investigate its authenticity.

The dead brother, however, was not only our correspondent's imaginary child; he also represented a rival whom she had regarded with hatred from the time of his birth. By far the greater number of all telepathic intimations relate to death or the possibility of death; when patients under analysis keep telling us of the frequency and infallibility of their gloomy forebodings, we can with equal regularity show them that they are fostering particularly strong death-wishes in their unconscious against their nearest relations and have long been thus suppressing them. The patient whose history I related in 1909¹ was an example to the point; he was called a 'carrion crow' by his relations. But when this kindly and highly intelligent man - who has since himself perished in the war - began to make progress towards recovery, he himself gave me considerable assistance in clearing up his own psychological conjuring tricks. In the same way, the account given in our first correspondent's letter, of how he and his three brothers had received the news of their youngest brother's death as a thing they had long been inwardly aware of, appears to need no other explanation. The elder brothers would all have been equally convinced of the superfluosity of the youngest arrival.

Here is another of our dreamer's 'visions' which will probably become more intelligible in the light of analytic knowledge. Women friends obviously had a great significance in her emotional life. Only recently the death of one of them was conveyed to her by a knocking at night on the bed of a room-mate in the sanatorium. Another friend had many years before married a widower with several (five) children. On the occasion of her visits to their house she regularly saw the apparition of a lady, who she could not help supposing was the husband's first wife; this did not at first permit of confirmation, and only became a matter of certainty with her seven years later, on the discovery of a fresh photograph of the dead woman. This achievement in the way of a vision on the part of our correspondent had the same intimate dependence on the family complexes familiar to us as had her presentiment of her brother's death. By identifying herself with her friend she could in the person of the latter find the fulfilment of her own wishes; for every eldest daughter of a numerous family builds up in her unconscious the phantasy of becoming her father's second wife by the death of her mother. If the mother is ill or dies, the eldest daughter takes her place as a matter of course in relation to her younger brothers and sisters, and may even take over some part of the functions of the wife in respect to the father. The unconscious wish fills in the other part.

¹ 'Notes upon a Case of Obsessional Neurosis'

I am now almost at the end of what I wish to say. I might, however, add the observation that the instances of telepathic messages or productions which have been discussed here are clearly connected with emotions belonging to the sphere of the Oedipus complex. This may sound startling; I do not intend to give it out as a great discovery, however. I would rather revert to the result we arrived at through investigating the dream I considered first. Telepathy has no relation to the essential nature of dreams; it cannot deepen in any way what we already understand of them through analysis. On the other hand, psycho-analysis may do something to advance the study of telepathy, in so far as, by the help of its interpretations, many of the puzzling characteristics of telepathic phenomena may be rendered more intelligible to us; or other, still doubtful, phenomena may for the first time definitely be ascertained to be of a telepathic nature.

There remains one element of the apparently intimate connection between telepathy and dreams which is not affected by any of these considerations: namely, the incontestable fact that sleep creates favourable conditions for telepathy. Sleep is not, it is true, indispensable to the occurrence of telepathic processes - whether they originate in messages or in unconscious activity. If you are not already aware of this, you will learn it from the instance given by our second correspondent, of the young man's message which came between nine and ten in the morning. We must add, however, that no one has a right to take exception to telepathic occurrences if the event and the intimation (or message) do not exactly coincide in astronomical time. It is perfectly conceivable that a telepathic message might arrive contemporaneously with the event and yet only penetrate to consciousness the following night during sleep (or even in waking life only after a while, during some pause in the activity of the mind). We are, as you know, of opinion that dream-formation itself does not necessarily wait for the onset of sleep before it begins. Often the latent dream-thoughts may have been being got ready during the whole day, till at night they find the contact with the unconscious wish that shapes them into a dream. But if the phenomenon of telepathy is only an activity of the unconscious mind, then, of course, no fresh problem lies before us. The laws of unconscious mental life may then be taken for granted as applying to telepathy.

Have I given you the impression that I am secretly inclined to support the reality of telepathy in the occult sense? If so, I should very much regret that it is so difficult to avoid giving such an impression. For in reality I have been anxious to be strictly impartial. I have every reason to be so, since I have no opinion on the matter and know nothing about it.

SOME NEUROTIC MECHANISMS IN JEALOUSY, PARANOIA AND HOMOSEXUALITY
(1922)

Intentionally left blank

SOME NEUROTIC MECHANISMS IN JEALOUSY, PARANOIA AND HOMOSEXUALITY

A

Jealousy is one of those affective states, like grief, that may be described as normal. If anyone appears to be without it, the inference is justified that it has undergone severe repression and consequently plays all the greater part in his unconscious mental life. The instances of abnormally intense jealousy met with in analytic work reveal themselves as constructed of three layers. The three layers or grades of jealousy may be described as (1) *competitive* or normal, (2) *projected*, and (3) *delusional* jealousy.

There is not much to be said from the analytic point of view. It is easy to see that essentially it is compounded of grief, the pain caused by the thought of losing the loved object, and of the narcissistic wound, in so far as this is distinguishable from the other wound; further, of feelings of enmity against the successful rival, and of a greater or lesser amount of self-criticism which tries to hold the subject's own ego accountable for his loss. Although we may call it normal, this jealousy is by no means completely rational, that is, derived from the actual situation, proportionate to the real circumstances and under the complete control of the conscious ego; for it is rooted deep in the unconscious, it is a continuation of the earliest stirrings of the child's affective life, and it originates in the Oedipus or brother-and-sister complex of the first sexual period. Moreover, it is noteworthy that in some people it is experienced bisexually. That is to say, a man will not only feel pain about the woman he loves and hatred of the man who is his rival, but also grief about the man, whom he loves unconsciously, and hatred of the woman as his rival; and this latter set of feelings will add to the intensity of his jealousy. I even know of a man who suffered exceedingly during his attacks of jealousy and who, according to his own account, went through unendurable torments by consciously imagining himself in the position of the faithless woman. The sensation of helplessness which then came over him and the images he used to describe his condition - exposed to the vulture's beak like Prometheus, or thrown bound into a nest of serpents - were referred by him to impressions received during several homosexual acts of aggression to which he had been subjected as a boy.

The jealousy of the second layer, *projected* jealousy, is derived in both men and women either from their own actual unfaithfulness in real life or from impulses towards it which have succumbed to repression. It is a matter of everyday experience that fidelity, especially that degree of it required in marriage, is only maintained in the face of continual temptations. Anyone who denies these temptations in himself will nevertheless feel their pressure so strongly that he will be glad enough to make use of an unconscious mechanism to alleviate his situation. He can obtain this alleviation - and, indeed, acquittal by his conscience - if he projects his own impulses to faithlessness on to the partner to whom he owes faith. This strong motive can then make use of the perceptual material which betrays unconscious impulses of the same kind in the partner, and the subject can justify himself with the reflection that the other is probably not much better than he is himself.¹

Social conventions have wisely taken this universal state of things into account, by granting a certain amount of latitude to the married woman's craving to attract and the married man's thirst to make conquests, in the expectation that this inevitable tendency to unfaithfulness will thus find a safety valve and be rendered innocuous. Convention has laid down that neither partner is to hold the other accountable for these little excursions in the direction of unfaithfulness, and they usually result in the desire that has been awakened by the new object finding satisfaction in some kind of return to faithfulness to the original object. A jealous person, however, does not recognize this convention of tolerance; he does not believe in any such thing as a halt or a turning-back once the path has been trodden, nor that a flirtation may be a safeguard against actual infidelity. In the treatment of a jealous person like this, one must refrain from disputing with him the material on which he bases his suspicions; one can only aim at bringing him to regard the matter in a different light.

¹ Cf. Desdemona's song:

I called my love false love; but what said he then?
If I court moe women, you'll couch with moe men.

The jealousy that arises from such a projection has, it is true, an almost delusional character; it is, however, amenable to the analytic work of exposing the unconscious phantasies of the subject's own infidelity. The position is worse as regards jealousy belonging to the third layer, the true *delusional* type. It too has its origin in repressed impulses towards unfaithfulness; but the object in these cases is of the same sex as the subject. Delusional jealousy is what is left of a homosexuality that has run its course, and it rightly takes its position among the classical forms of paranoia. As an attempt at defence against an unduly strong homosexual impulse it may, in a man, be described in the formula: 'I do not love him, *she* loves him!'¹ In a delusional case one will be prepared to find jealousy belonging to all three layers, never to the third alone.

B

Paranoia - Cases of paranoia are for well-known reasons not usually amenable to analytic investigation. I have recently been able, nevertheless, by an intensive study of two paranoics, to discover something new to me.

The first case was that of a youngish man with a fully developed paranoia of jealousy, the object of which was his impeccably faithful wife. A stormy period in which the delusion had possessed him uninterruptedly already lay behind him. When I saw him he was only subject to clearly separated attacks, which lasted for several days and which, curiously enough, regularly appeared on the day after he had had sexual intercourse with his wife, which was, incidentally, satisfying to both of them. The inference is justified that after every satiation of the heterosexual libido the homosexual component, likewise stimulated by the act, forced an outlet for itself in the attack of jealousy.

These attacks drew their material from his observation of minute indications, by which his wife's quite unconscious coquetry, unnoticeable to any one else, had betrayed itself to him. She had unintentionally touched the man sitting next her with her hand; she had turned too much towards him, or she had smiled more pleasantly than when alone with her husband. He was extraordinarily observant of all these manifestations of her unconscious, and always knew how to interpret them correctly, so that he really was always in the right about it, and could furthermore call in analysis to justify his jealousy. His abnormality really reduced itself to this, that he watched his wife's unconscious mind much more closely and then regarded it as far more important than anyone else would have thought of doing.

¹ See the Schreber analysis (1911c).

We are reminded that sufferers from persecutory paranoia act in just the same way. They, too, cannot regard anything in other people as indifferent, and they, too, take up minute indications with which these other, unknown, people present them, and use them in their delusions of reference. The meaning of their delusion of reference is that they expect from all strangers something like love. But these people show them nothing of the kind; they laugh to themselves, flourish their sticks, even spit on the ground as they go by - and one really does not do such things while a person in whom one takes a friendly interest is near. One does them only when one feels quite indifferent to the passer-by, when one can treat him like air; and, considering, too, the fundamental kinship of the concepts of 'stranger' and 'enemy', the paranoid is not so far wrong in regarding this indifference as hate, in contrast to his claim for love.

We begin to see that we describe the behaviour of both jealous and persecutory paranoids very inadequately by saying that they project outwards on to others what they do not wish to recognize in themselves. Certainly they do this; but they do not project it into the blue, so to speak, where there is nothing of the sort already. They let themselves be guided by their knowledge of the unconscious, and displace to the unconscious minds of others the attention which they have withdrawn from their own. Our jealous husband perceived his wife's unfaithfulness instead of his own; by becoming conscious of hers and magnifying it enormously he succeeded in keeping his own unconscious. If we accept his example as typical, we may infer that the enmity which the persecuted paranoid sees in others is the reflection of his own hostile impulses against them. Since we know that with the paranoid it is precisely the most loved person of his own sex that becomes his persecutor, the question arises where this reversal of affect takes its origin; the answer is not far to seek - the ever-present ambivalence of feeling provides its source and the non-fulfilment of his claim for love strengthens it. This ambivalence thus serves the same purpose for the persecuted paranoid as jealousy served for my patient - that of a defence against homosexuality.

The dreams of my jealous patient presented me with a great surprise. They were not simultaneous with the outbreaks of the attacks, it is true, but they occurred within the period which was under the dominance of the delusion; yet they were completely free from delusion and they revealed the underlying homosexual impulses with no more than the usual degree of disguise. Since I had had little experience of the dreams of paranoics, it seemed plausible at the time to suppose that it was true in general that paranoia does not penetrate into dreams.

This patient's homosexual position was easily surveyed. He had made no friendships and developed no social interests; one had the impression that only the delusion had carried forward the development of his relations with men, as if it had taken over some of the arrears that had been neglected. The fact that his father was of no great importance in the family, combined with a humiliating homosexual trauma in early boyhood, had forced his homosexuality into repression and barred the way to its sublimation. The whole of his youth was governed by a strong attachment to his mother. Of all her many sons he was her declared favourite, and he developed marked jealousy of the normal type in regard to her. When later he made his choice of a wife - mainly prompted by an impulse to enrich his mother - his longing for a virgin mother expressed itself in obsessive doubts about his fiancée's virginity. The first years of his marriage were free from jealousy. Then he became unfaithful to his wife and entered upon an intimate relationship with another woman that lasted for a considerable time. Frightened by a certain suspicion, he at length made an end of this love affair, and not until then did jealousy of the second, projected type break out, by means of which he was able to assuage his self-reproaches about his own unfaithfulness. It was soon complicated by an accession of homosexual impulses, of which his father-in-law was the object, and became a fully formed jealous paranoia.

My second case would probably not have been classified as persecutory paranoia, apart from analysis; but I had to recognize the young man as a candidate for a terminal illness of that kind. In his attitude to his father there existed an ambivalence which in its range was quite extraordinary. On the one hand, he was the most pronounced rebel imaginable, and had developed manifestly in every direction in opposition to his father's wishes and ideals; on the other hand, at a deeper level he was still the most submissive of sons, who after his father's death denied himself all enjoyment of women out of a tender sense of guilt. His actual relations with men were clearly dominated by suspiciousness; his keen intellect easily rationalized this attitude; and he knew how to bring it about that both friends and acquaintances deceived and exploited him. The new thing I learned from studying him was that classical persecutory ideas may be present without finding belief or acceptance. They flashed up occasionally during the analysis, but he regarded them as unimportant and invariably scoffed at them. This may occur in many cases of paranoia; it may be that the delusions which we regard as new formations when the disease breaks out have already long been in existence.

It seems to me that we have here an important discovery - namely, that the qualitative factor, the presence of certain neurotic formations, has less practical significance than the quantitative factor, the degree of attention or, more correctly, the amount of cathexis that these structures are able to attract to themselves. Our consideration of the first case, the jealous paranoia, led to a similar estimate of the importance of the quantitative factor, by showing that there also the abnormality essentially consisted in the hypercathexis of the interpretations of someone else's unconscious. We have long known of an analogous fact in the analysis of hysteria. The pathogenic phantasies, derivatives of repressed instinctual impulses, are for a long time tolerated alongside the normal life of the mind, and have no pathogenic effect until by a revolution in the libidinal economy they receive a hypercathexis; not till then does the conflict which leads to the formation of symptoms break out. Thus as our knowledge grows we are increasingly impelled to bring the *economic* point of view into the foreground. I should also like to throw out the question whether this quantitative factor that I am now dwelling on does not suffice to cover the phenomena which Bleuler and others have lately proposed to name 'switching'. One need only assume that an increase in resistance in the course taken by the psychological current in one direction results in a hypercathexis of another path and thus causes the flow to be switched into that path.

My two cases of paranoia showed an instructive contrast in the behaviour of their dreams. Whereas those of the first case were free from delusion, as has already been said, the other patient produced great numbers of persecutory dreams, which may be regarded as forerunners of or substitutes for the delusional ideas. The pursuer, whom he only managed to escape with great fear, was usually a powerful bull or some other male symbol which even in the dream itself he sometimes recognized as representing his father. One day he produced a very characteristic paranoid transference-dream. He saw me shaving in front of him, and from the scent he realized that I was using the same soap as his father had used. I was doing this in order to oblige him to make a father-transference on to me. The choice of this incident for his dream quite unmistakably betrays the patient's depreciatory attitude to his paranoid phantasies and his disbelief in them; for his own eyes could tell him every day that I was never in a position to make use of shaving-soap and that therefore there was in this respect nothing to which a father-transference could attach itself.

A comparison of the dreams of the two patients shows, however, that the question whether or not paranoia (or any other psychoneurosis) can penetrate into dreams is based on a false conception of dreams. Dreams are distinguished from waking thought by the fact that they can include material (belonging to the region of the repressed) which must not emerge in waking thought. Apart from this, dreams are merely a *form of thinking*, a transformation of preconscious material of thought by the dream-work and its conditions. Our terminology of the neuroses is not applicable to repressed material; this cannot be called hysterical, nor obsessional, nor paranoid. As against this, the other part of the material which is subjected to the process of dream-formation - the preconscious thoughts - may be normal or may bear the character of any neurosis; they may be the products of any of the pathogenic processes in which the essence of a neurosis lies. There seems to be no reason why any such pathological idea should not be transformed into a dream. A dream may therefore quite simply represent a hysterical phantasy, an obsessional idea, or a delusion - that is, may reveal one or other of these upon interpretation. Observation of the two paranoids shows that the dreams of the one were quite normal while he was subject to his delusion, and that those of the other were paranoid in content while he was treating his delusional ideas with contempt. In both cases, therefore, the dream took up the material that was at the time forced into the background in waking life. This too, however, need not necessarily be an invariable rule.

C

Homosexuality. - Recognition of the organic factor in homosexuality does not relieve us of the obligation of studying the psychical processes connected with its origin. The typical process, already established in innumerable cases, is that a few years after the termination of puberty a young man, who until this time has been strongly fixated to his mother, changes his attitude; he identifies himself with his mother, and looks about for love-objects in whom he can re-discover himself, and whom he might then love as his mother loved him. The characteristic mark of this process is that for several years one of the necessary conditions for his love is usually that the male object shall be of the same age as he himself was when the change took place. We have come to know of various factors contributing to this result, probably in different degrees. First there is the fixation on the mother, which makes it difficult to pass on to another woman. Identification with the mother is an outcome of this attachment, and at the same time in a certain sense it enables the son to keep true to her, his first object. Then there is the inclination towards a narcissistic object-choice, which in general lies readier to hand and is easier to put into effect than a move towards the other sex. Behind this latter factor there lies concealed another of quite exceptional strength, or perhaps it coincides with it: the high value set upon the male organ and the inability to tolerate its absence in a love-object. Depreciation of women, and aversion to them, even horror of them, are generally derived from the early discovery that women have no penis. We subsequently discovered, as another powerful motive urging towards homosexual object-choice, regard for the father or fear of him; for the renunciation of women means that all rivalry with him (or with all men who may take his place) is avoided. The two last motives - the clinging to the condition of a penis in the object, as well as the retiring in favour of the father - may be ascribed to the castration complex. Attachment to the mother, narcissism, fear of castration - these are the factors (which incidentally have nothing specific about them) that we have hitherto found in the psychical aetiology of homosexuality; and with these must be reckoned the effect of seduction, which is responsible for a premature fixation of the libido, as well as the influence of the organic factor which favours the passive role in love.

We have, however, never regarded this analysis of the origin of homosexuality as complete. I can now point to a new mechanism leading to homosexual object-choice, although I cannot say how large a part it plays in the formation of the extreme, manifest and exclusive type of homosexuality. Observation has directed my attention to several cases in which during early childhood impulses of jealousy, derived from the mother-complex and of very great intensity, arose against rivals, usually older brothers. This jealousy led to an exceedingly hostile and aggressive attitude towards these brothers which might sometimes reach the pitch of actual death-wishes, but which could not maintain themselves in the face of the subject's further development. Under the influences of upbringing - and certainly not uninfluenced also by their own continuing powerlessness - these impulses yielded to repression and underwent a transformation, so that the rivals of the earlier period became the first homosexual love-objects. Such an outcome of the attachment to the mother shows various interesting relations with other processes known to us. First of all it is a complete contrast to the development of persecutory paranoia, in which the person who has before been loved becomes the hated persecutor, whereas here the hated rivals are transformed into love objects. It represents, too, an exaggeration of the process which, according to my view, leads to the birth of social instincts in the individual.¹ In both processes there is first the presence of jealous and hostile impulses which cannot achieve satisfaction; and both the affectionate and the social feelings of identification arise as reactive formations against the repressed aggressive impulses.

¹ Cf. my *Group psychology and the Analysis of the Ego* (1921c).

This new mechanism of homosexual object-choice - its origin in rivalry which has been overcome and in aggressive impulses which have become repressed - is sometimes combined with the typical conditions already familiar to us. In the history of homosexuals one often hears that the change in them took place after the mother had praised another boy and set him up as a model. The tendency to a narcissistic object-choice was thus stimulated, and after a short phase of keen jealousy the rival became a love-object. As a rule, however, the new mechanism is distinguished by the change taking place at a much earlier period, and the identification with the mother receding into the background. Moreover, in the cases I have observed, it led only to homosexual attitudes which did not exclude heterosexuality and did not involve a *horror feminae*.

It is well known that a good number of homosexuals are characterized by a special development of their social instinctual impulses and by their devotion to the interests of the community. It would be tempting, as a theoretical explanation of this, to say that the behaviour towards men in general of a man who sees in other men potential love-objects must be different from that of a man who looks upon other men in the first instance as rivals in regard to women. The only objection to this is that jealousy and rivalry play their part in homosexual love as well, and that the community of men also includes these potential rivals. Apart from this speculative explanation, however, the fact that homosexual object-choice not infrequently proceeds from an early overcoming of rivalry with men cannot be without a bearing on the connection between homosexuality and social feeling.

In the light of psycho-analysis we are accustomed to regard social feeling as a sublimation of homosexual attitudes towards objects. In the homosexuals with marked social interests, it would seem that the detachment of social feeling from object choice has not been fully carried through.

TWO ENCYCLOPAEDIA ARTICLES

(A) PSYCHO-ANALYSIS

Psycho-analysis is the name (1) of a procedure for the investigation of mental processes which are almost inaccessible in any other way, (2) of a method (based upon that investigation) for the treatment of neurotic disorders and (3) of a collection of psychological information obtained along those lines, which is gradually being accumulated into a new scientific discipline.

History - The best way of understanding psycho-analysis is still by tracing its origin and development. In 1880 and 1881 Dr. Josef Breuer of Vienna, a well-known physician and experimental physiologist, was occupied in the treatment of a girl who had fallen ill of a severe hysteria while she was nursing her sick father. The clinical picture was made up of motor paralyses, inhibitions, and disturbances of consciousness. Following a hint given him by the patient herself, who was a person of great intelligence, he put her into a state of hypnosis and contrived that, by describing to him the moods and thoughts that were uppermost in her mind, she returned on each particular occasion to a normal mental condition. By consistently repeating the same laborious process, he succeeded in freeing her from all her inhibitions and paralyses, so that in the end he found his trouble rewarded by a great therapeutic success as well as by an unexpected insight into the nature of the puzzling neurosis. Nevertheless, Breuer refrained from following up his discovery or from publishing anything about the case until some ten years later, when the personal influence of the present writer (Freud, who had returned to Vienna in 1886 after studying in the school of Charcot) prevailed on him to take up the subject afresh and embark upon a joint study of it. These two, Breuer and Freud, published a preliminary paper 'On the Psychical Mechanism of Hysterical Phenomena' in 1893, and in 1895 a volume entitled *Studies on Hysteria* (which reached its fourth edition in 1922), in which they described their therapeutic procedure as '*cathartic*'.

Catharsis. - The investigations which lay at the root of Breuer and Freud's studies led to two chief results, and these have not been shaken by subsequent experience: first, that hysterical symptoms have sense and meaning, being substitutes for normal mental acts; and secondly, that the uncovering of this unknown meaning is accompanied by the removal of the symptoms - so that in this case scientific research and therapeutic effort coincide. The observations were carried out upon a series of patients who were treated in the same manner as Breuer's first patient, that is to say, put into a state of deep hypnosis; and the results seemed brilliant, until later their weak side became evident. The theoretical ideas put forward at that time by Breuer and Freud were influenced by Charcot's theories on traumatic hysteria and could find support in the findings of his pupil Pierre Janet, which, though they were published earlier than the *Studies*, were in fact subsequent to Breuer's first case. From the very beginning the factor of *affect* was brought into the foreground: hysterical symptoms, the authors maintained, came into existence when a mental process with a heavy charge of affect was in any way prevented from being levelled out along the normal path leading to consciousness and movement (i. e. was prevented from being '*abreacted*'); as a result of this the affect, which was in a sense '*strangled*', was diverted along wrong paths and flowed off into the somatic innervation (a process named '*conversion*'). The occasions upon which 'pathogenic ideas' of this kind arose were described by Breuer and Freud as '*psychical traumas*', and, since these often dated back to the very remote past, it was possible for the authors to say that hysterics suffered mainly from reminiscences (which had not been dealt with). Under the treatment, therefore, '*catharsis*' came about when the path to consciousness was opened and there was a normal discharge of affect. It will be seen that an essential part of this theory was the assumption of the existence of *unconscious* mental processes. Janet too had made use of unconscious acts in mental life; but, as he insisted in his later polemics against psycho-analysis, to him the phrase was no more than a make-shift expression, a '*manière de parler*', and he intended to suggest no new point of view by it.

In a theoretical section of the *Studies* Breuer brought forward some speculative ideas about the processes of excitation in the mind. These ideas determined the direction of future lines of thought and even to-day have not received sufficient appreciation. But they brought his contributions to this branch of science to an end, and soon afterwards he withdrew from the common work.

Transition to Psycho-analysis. - Contrasts between the views of the two authors had been visible even in the *Studies*. Breuer supposed that the pathogenic ideas produced their traumatic effect because they arose during '*hypnoid states*', in which mental functioning was subject to special limitations. The present writer rejected this explanation and inclined to the belief that an idea became pathogenic if its content was in opposition to the predominant trend of the subject's mental life so that it provoked him into '*defence*'. (Janet had attributed to hysterical patients a constitutional incapacity for holding together the contents of their minds; and it was at this point that his path diverged from that of Breuer and Freud.) Moreover, the two innovations which led the present writer to move away from the cathartic method had already been mentioned in the *Studies*. After Breuer's withdrawal they became the starting-point of fresh developments.

Abandonment of Hypnosis. - The first of these innovations was based on practical experience and led to a change in technique. The second consisted in an advance in the clinical understanding of neuroses. It soon appeared that the therapeutic hopes which had been placed upon cathartic treatment in hypnosis were to some extent unfulfilled. It was true that the disappearance of the symptoms went hand-in-hand with the catharsis, but total success turned out to be entirely dependent upon the patient's relation to the physician and thus resembled the effect of '*suggestion*'. If that relation was disturbed, all the symptoms reappeared, just as though they had never been cleared up. In addition to this, the small number of people who could be put into a deep state of hypnosis involved a very considerable limitation, from the medical standpoint, of the applicability of the cathartic procedure. For these reasons the present writer decided to give up the use of hypnosis. But at the same time the impressions he had derived from hypnosis afforded him the means of replacing it.

Free Association. - The effect of the hypnotic condition upon the patient had been so greatly to increase his ability to make associations that he was able straight away to find the path - inaccessible to his conscious reflection - which led from the symptom to the thoughts and memories connected with it. The abandonment of hypnosis seemed to make the situation hopeless, until the writer recalled a remark of Bernheim's to the effect that things that had been experienced in a state of somnambulism were only *apparently* forgotten and that they could be brought into recollection at any time if the physician insisted forcibly enough that the patient knew them. The writer therefore endeavoured to insist on his *unhypnotized* patients giving him their associations, so that from the material thus provided he might find the path leading to what had been forgotten or fended off. He noticed later that the insistence was unnecessary and that copious ideas almost always arose in the patient's mind, but that they were held back from being communicated and even from becoming conscious by certain objections put by the patient in his own way. It was to be expected - though this was still unproved and not until later confirmed by wide experience - that everything that occurred to a patient setting out from a particular starting-point must also stand in an internal connection with that starting-point; hence arose the technique of educating the patient to give up the whole of his critical attitude and of making use of the material which was thus brought to light for the purpose of uncovering the connections that were being sought. A strong belief in the strict determination of mental events certainly played a part in the choice of this technique as a substitute for hypnosis.

The '*Fundamental Technical Rule*' of this procedure of 'free association' has from that time on been maintained in psycho-analytic work. The treatment is begun by the patient being required to put himself in the position of an attentive and dispassionate self-observer, merely to read off all the time the surface of his consciousness, and on the one hand to make a duty of the most complete honesty while on the other not to hold back any idea from communication, even if (1) he feels that it is too disagreeable or if (2) he judges that it is nonsensical or (3) too unimportant or (4) irrelevant to what is being looked for. It is uniformly found that precisely those ideas which provoke these last-mentioned reactions are of particular value in discovering the forgotten material.

Psycho-analysis as an Interpretive Art. - The new technique altered the picture of the treatment so greatly, brought the physician into such a new relation to the patient and produced so many surprising results that it seemed justifiable to distinguish the procedure from the cathartic method by giving it a new name. The present writer gave this method of treatment, which could now be extended to many other forms of neurotic disorder, the name of *psycho-analysis*. Now, in the first resort, this psycho-analysis was an art of *interpretation* and it set itself the task of carrying deeper the first of Breuer's great discoveries - namely, that neurotic symptoms are significant substitutes for other mental acts which have been omitted. It was now a question of regarding the material produced by the patients' associations as though it hinted at a hidden meaning and of discovering that meaning from it. Experience soon showed that the attitude which the analytic physician could most advantageously adopt was to surrender himself to his own unconscious mental activity, in a state of *evenly suspended attention*, to avoid so far as possible reflection and the construction of conscious expectations, not to try to fix anything that he heard particularly in his memory, and by these means to catch the drift of the patient's unconscious with his own unconscious. It was then found that, except under conditions that were too unfavourable, the patient's associations emerged like allusions, as it were, to one particular theme and that it was only necessary for the physician to go a step further in order to guess the material which was concealed from the patient himself and to be able to communicate it to him. It is true that this work of interpretation was not to be brought under strict rules and left a great deal of play to the physician's tact and skill; but, with impartiality and practice, it was usually possible to obtain trustworthy results - that is to say, results which were confirmed by being repeated in similar cases. At a time when so little was as yet known of the unconscious, the structure of the neuroses and the pathological processes underlying them, it was a matter for satisfaction that a technique of this kind should be available, even if it had no better theoretical basis. Moreover it is still employed in analyses at the present day in the same manner, though with a sense of greater assurance and with a better understanding of its limitations.

The Interpretation of Parapraxes and Haphazard Acts. - It was a triumph for the interpretative art of psycho-analysis when it succeeded in demonstrating that certain common mental acts of normal people, for which no one had hitherto attempted to put forward a psychological explanation, were to be regarded in the same light as the symptoms of neurotics: that is to say, they had a *meaning*, which was unknown to the subject but which could easily be discovered by analytic means. The phenomena in question were such events as the temporary forgetting of familiar words and names, forgetting to carry out prescribed tasks, everyday slips of the tongue and of the pen, misreadings, losses and mislayings of objects, certain errors, instances of apparently accidental self-injury, and finally habitual movements carried out seemingly without intention or in play, tunes hummed 'thoughtlessly', and so on. All of these were shorn of their physiological explanation, if any such had ever been attempted, were shown to be strictly determined and were revealed as an expression of the subject's suppressed intentions or as a result of a clash between two intentions one of which was permanently or temporarily unconscious. The importance of this contribution to psychology was of many kinds. The range of mental determinism was extended by it in an unforeseen manner; the supposed gulf between normal and pathological mental events was narrowed; in many cases a useful insight was afforded into the play of mental forces that must be suspected to lie behind the phenomena. Finally, a class of material was brought to light which is calculated better than any other to stimulate a belief in the existence of unconscious mental acts even in people to whom the hypothesis of something at once mental and unconscious seems strange and even absurd. The study of one's own parapraxes and haphazard acts, for which most people have ample opportunities, is even to-day the best preparation for an approach to psycho-analysis. In analytic treatment, the interpretation of parapraxes retains a place as a means of uncovering the unconscious, alongside the immeasurably more important interpretation of associations.

The Interpretation of Dreams. - A new approach to the depths of mental life was opened when the technique of free association was applied to dreams, whether one's own or those of patients in analysis. In fact, the greater and better part of what we know of the processes in the unconscious levels of the mind is derived from the interpretation of dreams. Psycho-analysis has restored to dreams the importance which was generally ascribed to them in ancient times, but it treats them differently. It does not rely upon the cleverness of the dream-interpreter but for the most part hands the task over to the dreamer himself by asking him for his associations to the separate elements of the dream. By pursuing these associations further we obtain knowledge of thoughts which coincide entirely with the dream but which can be recognized - up to a certain point - as genuine and completely intelligible portions of waking mental activity. Thus the recollected dream emerges as the *manifest dream content*, in contrast to the *latent dream-thoughts* discovered by interpretation. The process which has transformed the latter into the former, that is to say into 'the dream', and which is undone by the work of interpretation, may be called the '*dream-work*'.

We also describe the latent dream-thoughts, on account of their connection with waking life, as '*residues of the day*'. By the operation of the dream-work (to which it would be quite incorrect to ascribe any 'creative' character) the latent dream thoughts are *condensed* in a remarkable way, are *distorted* by the *displacement* of psychical intensities and are arranged with a view to being *represented in visual pictures*; and, besides all this, before the manifest dream is arrived at, they are submitted to a process of *secondary revision* which seeks to give the new product something in the nature of sense and coherence. Strictly speaking, this last process does not form a part of the dream-work.

The Dynamic Theory of Dream-Formation. The motive power for the formation of dreams is not provided by the latent dream-thoughts or day's residues, but by an unconscious impulse, repressed during the day, with which the day's residues have been able to establish contact and which contrives to make a *wish-fulfilment* for itself out of the material of the latent thoughts. Thus every dream is on the one hand the fulfilment of a wish on the part of the unconscious and on the other hand (in so far as it succeeds in guarding the state of sleep against being disturbed) the fulfilment of the normal wish to sleep which set the sleep going. If we disregard the unconscious contribution to the formation of the dream and limit the dream to its latent thoughts, it can represent anything with which waking life has been concerned - a reflection, a warning, an intention, a preparation for the immediate future or, once again, the satisfaction of an unfulfilled wish. The unrecognizability, strangeness and absurdity of the manifest dream are partly the result of the translation of the thoughts into a different, so to say *archaic*, method of expression, but partly the effect of a restrictive, critically disapproving agency in the mind which does not entirely cease to function during sleep. It is plausible to suppose that the '*dream-censorship*', which we regard as being responsible in the first instance for the distortion of the dream-thoughts into the manifest dream, is an expression of the same mental forces which during the day-time had held back or *repressed* the unconscious wishful impulse.

It has been worth while to enter in some detail into the explanation of dreams, since analytic work has shown that the dynamics of the formation of dreams are the same as those of the formation of symptoms. In both cases we find a struggle between two trends, of which one is unconscious and ordinarily repressed and strives towards satisfaction - that is, wish-fulfilment - while the other, belonging probably to the conscious ego, is disapproving and repressive. The outcome of this conflict is a *compromise-formation* (the dream or the symptom) in which both trends have found an incomplete expression. The theoretical importance of this conformity between dreams and symptoms is illuminating. Since dreams are not pathological phenomena, the fact shows that the mental mechanisms which produce the symptoms of illness are equally present in normal mental life, that the same uniform law embraces both the normal and the abnormal and that the findings of research into neurotics or psychotics cannot be without significance for our understanding of the healthy mind.

Symbolism. - In the course of investigating the form of expression brought about by the dream-work, the surprising fact emerged that certain objects, arrangements and relations are represented, in a sense indirectly, by 'symbols', which are used by the dreamer without his understanding them and to which as a rule he offers no associations. Their translation has to be provided by the analyst, who can himself only discover it empirically by experimentally fitting it into the context. It was later found that linguistic usage, mythology and folklore afford the most ample analogies to dream-symbols. Symbols, which raise the most interesting and hitherto unsolved problems, seem to be a fragment of extremely ancient inherited mental equipment. The use of a common symbolism extends far beyond the use of a common language.

The Aetiological Significance of Sexual Life. - The second novelty which emerged after the hypnotic technique had been replaced by free associations was of a clinical nature. It was discovered in the course of the prolonged search for the traumatic experiences from which hysterical symptoms appeared to be derived. The more carefully the search was pursued the more extensive seemed to be the network of aetiologically significant impressions involved, but the further back, too, did they reach into the patient's puberty or childhood. At the same time they assumed a uniform character and eventually it became inevitable to bow before the evidence and recognize that at the root of the formation of every symptom there were to be found traumatic experiences from early sexual life. Thus a sexual trauma stepped into the place of an ordinary trauma and the latter was seen to owe its aetiological significance to an associative or symbolic connection with the former, which had preceded it. An investigation of cases of common nervousness (falling into the two classes of *neurasthenia* and *anxiety neurosis*) which was simultaneously undertaken led to the conclusion that these disorders could be traced to *contemporary* abuses in the patients' sexual life and could be removed if these were brought to an end. It was thus easy to infer that neuroses in general are an expression of disturbances in sexual life, the so-called *actual-neuroses* being the consequences (by chemical agency) of *contemporary* injuries and the *psycho-neuroses* the consequences (by psychical modification) of *bygone* injuries to a biological function which had hitherto been gravely neglected by science. None of the theses of psycho-analysis has met with such tenacious scepticism or such embittered resistance as this assertion of the preponderating aetiological significance of sexual life in the neuroses. It should, however, be expressly remarked that, in its development up to the present day, psycho-analysis has found no reason to retreat from this opinion.

Infantile Sexuality. - As a result of its aetiological researches, psycho-analysis found itself in the position of dealing with a subject the very existence of which had scarcely been suspected previously. Science had become accustomed to consider sexual life as beginning with puberty and regarded manifestations of sexuality in children as rare signs of abnormal precocity and degeneracy. But now psycho-analysis revealed a wealth of phenomena, remarkable, yet of regular occurrence, which made it necessary to date back the beginning of the sexual function in children almost to the commencement of extra-uterine existence; and it was asked with astonishment how all this could have come to be overlooked. The first glimpses of sexuality in children had indeed been obtained through the analytic examination of adults and were consequently saddled with all the doubts and sources of error that could be attributed to such a belated retrospect; but subsequently (from 1908 onwards) a beginning was made with the analysis of children themselves and with the unembarrassed observation of their behaviour, and in this way direct confirmation was reached for the whole factual basis of the new view.

Sexuality in children showed a different picture in many respects from that in adults, and, surprisingly enough, it exhibited numerous traces of what, in adults, were condemned as '*perversions*'. It became necessary to enlarge the concept of what was sexual, till it covered more than the impulsion towards the union of the two sexes in the sexual act or towards provoking particular pleasurable sensations in the genitals. But this enlargement was rewarded by the new possibility of grasping infantile, normal and perverse sexual life as a single whole.

The analytic researches carried out by the writer fell, to begin with, into the error of greatly overestimating the importance of *seduction* as a source of sexual manifestations in children and as a root for the formation of neurotic symptoms. This misapprehension was corrected when it became possible to appreciate the extraordinarily large part played in the mental life of neurotics by the activities of *phantasy*, which clearly carried more weight in neurosis than did external reality. Behind these phantasies there came to light the material which allows us to draw the picture which follows of the development of the sexual function.

The Development of the Libido. - The sexual instinct, the dynamic manifestation of which in mental life we shall call '*libido*', is made up of component instincts into which it may once more break up and which are only gradually united into well-defined organizations. The sources of these component instincts are the organs of the body and in particular certain specially marked *erotogenic zones*; but contributions are made to libido from every important functional process in the body. At first the individual component instincts strive for satisfaction independently of one another, but in the course of development they become more and more convergent and concentrated. The first (pregenital) stage of organization to be discerned is the *oral* one, in which - in conformity with the suckling's predominant interest - the oral zone plays the leading part. This is followed by the *sadistic-anal* organization, in which the *anal* zone and the component instinct of *sadism* are particularly prominent; at this stage the difference between the sexes is represented by the contrast between active and passive. The third and final stage of organization is that in which the majority of the component instincts converge under the *primacy of the genital zones*. As a rule this development is passed through swiftly and unobtrusively; but some individual portions of the instincts remain behind at the prodromal stages of the process and thus give rise to *fixations* of libido, which are important as constituting predispositions for subsequent irruptions of repressed impulses and which stand in a definite relation to the later development of neuroses and perversions. (See the article on 'The Libido Theory'.)

The Process of Finding an Object, and the Oedipus Complex. - In the first instance the oral component instinct finds satisfaction by attaching itself to the sating of the desire for nourishment; and its object is the mother's breast. It then detaches itself, becomes independent and at the same time *auto-erotic*, that is, it finds an object in the child's own body. Others of the component instincts also start by being auto-erotic and are not until later diverted on to an external object. It is a particularly important fact that the component instincts belonging to the genital zone habitually pass through a period of intense auto-erotic satisfaction. The component instincts are not all equally serviceable in the final genital organization of libido; some of them (for instance, the anal components) are consequently left aside and suppressed, or undergo complicated transformations.

In the very earliest years of childhood (approximately between the ages of two and five) a convergence of the sexual impulses occurs of which, in the case of boys, the object is the mother. This choice of an object, in conjunction with a corresponding attitude of rivalry and hostility towards the father, provides the content of what is known as the *Oedipus complex*, which in every human being is of the greatest importance in determining the final shape of his erotic life. It has been found to be characteristic of a normal individual that he learns to master his Oedipus complex, whereas the neurotic subject remains involved in it.

The Diphasic Onset of Sexual Development. - Towards the end of the fifth year this early period of sexual life normally comes to an end. It is succeeded by a period of more or less complete *latency*, during which ethical restraints are built up, to act as defences against the desires of the Oedipus complex. In the subsequent period of *puberty*, the Oedipus complex is revived in the unconscious and embarks upon further modifications. It is only at puberty that the sexual instincts develop to their full intensity; but the direction of that development, as well as all the predispositions for it, have already been determined by the early efflorescence of sexuality during childhood which preceded it. This diphasic development of the sexual function - in two stages, interrupted by the latency period - appears to be a biological peculiarity of the human species and to contain the determining factor for the origin of neuroses.

The Theory of Repression. - These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not *ego-syntonic*, the ego has *repressed* them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of *resistance*. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their dammed-up libido finds other ways out from the unconscious: for it *regresses* to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libidinal development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a *symptom* and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-instincts; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction-formations, which are assurances against sexual satisfaction.

Transference. - If further proof were needed of the truth that the motive forces behind the formation of neurotic symptoms are of a sexual nature, it would be found in the fact that in the course of analytic treatment a special emotional relation is regularly formed between the patient and the physician. This goes far beyond rational limits. It varies between the most affectionate devotion and the most obstinate enmity and derives all of its characteristics from earlier erotic attitudes of the patient's which have become unconscious. This *transference* alike in its positive and in its negative form is used as a weapon by the resistance; but in the hands of the physician it becomes the most powerful therapeutic instrument and it plays a part scarcely to be over-estimated in the dynamics of the process of cure.

The Corner-Stones of Psycho-Analytic Theory. - The assumption that there are unconscious mental processes, the recognition of the theory of resistance and repression, the appreciation of the importance of sexuality and of the Oedipus complex - these constitute the principal subject-matter of psycho-analysis and the foundations of its theory. No one who cannot accept them all should count himself a psycho-analyst.

Later History of Psycho-Analysis. - Psycho-analysis was carried approximately thus far by the work of the writer of this article, who for more than ten years was its sole representative. In 1906 the Swiss psychiatrists Bleuler and C. G. Jung began to play a lively part in analysis; in 1907 a first conference of its supporters took place at Salzburg; and the young science soon found itself the centre of interest both among psychiatrists and laymen. Its reception in Germany, with her morbid craving for authority, was not precisely to the credit of German science and moved even so cool a partisan as Bleuler to an energetic protest. Yet no condemnation or dismissal at official congresses served to hold up the internal growth or external expansion of psycho-analysis. In the course of the next ten years it extended far beyond the frontiers of Europe and became especially popular in the United States of America, and this was due in no small degree to the advocacy and collaboration of Putnam (Boston), Ernest Jones (Toronto; later London), Fournoy (Geneva), Ferenczi (Budapest), Abraham (Berlin), and many others besides. The anathema which was imposed upon psycho-analysis led its supporters to combine in an international organization which in the present year (1922) is holding its eighth private Congress in Berlin and now includes local groups in Vienna, Budapest, Berlin, Holland, Zurich, London, New York, Calcutta and Moscow. This development was not interrupted even by the World War. In 1918-19 Dr. Anton von Freund of Budapest founded the Internationaler Psychoanalytischer Verlag, which publishes journals and books concerned with psycho analysis, and in 1920 Dr. M. Eitingon opened in Berlin the first psycho-analytic clinic for the treatment of neurotics without private means. Translations of the writer's principal works, which are now in preparation, into French, Italian and Spanish, testify to a growing interest in psycho-analysis in the Latin world as well.

Between 1911 and 1913 two movements of divergence from psycho-analysis took place, evidently with the object of mitigating its repellent features. One of these (sponsored by C. G. Jung), in an endeavour to conform to ethical standards, divested the Oedipus complex of its real significance by giving it only a *symbolic* value, and in practice neglected the uncovering of the forgotten and, as we may call it, 'prehistoric' period of childhood. The other (originated by Alfred Adler in Vienna) reproduced many factors from psycho-analysis under other names - repression, for instance, appeared in a sexualized version as the 'masculine protest'. But in other respects it turned away from the unconscious and the sexual instincts, and endeavoured to trace back the development of character and of the neuroses to the 'will to power', which by means of overcompensation strives to check the dangers arising from 'organ inferiority'. Neither of these movements, with their systematic structures, had any permanent influence on psycho-analysis. In the case of Adler's theories it soon became clear that they had very little in common with psycho-analysis, which they were designed to replace.

More Recent Advances in Psycho-Analysis. - Since psycho-analysis has become the field of work for such a large number of observers it has made advances, both in extent and depth; but unfortunately these can receive only the briefest mention in the present article.

Narcissism. - The most important theoretical advance has certainly been the application of the libido theory to the repressing ego. The ego itself came to be regarded as a reservoir of what was described as narcissistic libido, from which the libidinal cathexes of objects flowed out and into which they could be once more withdrawn. By the help of this conception it became possible to embark upon the analysis of the ego and to make a clinical distinction of the psychoneuroses into *transference neuroses* and *narcissistic disorders*. In the former (hysteria and obsessional neurosis) the subject has at his disposal a quantity of libido striving to be transferred on to extraneous objects, and use is made of this in carrying out analytic treatment; on the other hand, the narcissistic disorders (dementia praecox, paranoia, melancholia) are characterized by a withdrawal of the libido from objects and they are therefore scarcely accessible to analytic therapy. But their therapeutic inaccessibility has not prevented analysis from making the most fruitful beginnings in the deeper study of these illnesses, which are counted among the psychoses.

Development of Technique. - After the analyst's curiosity had, as it were, been gratified by the elaboration of the technique of interpretation, it was inevitable that interest should turn to the problem of discovering the most effective way of influencing the patient. It soon became evident that the physician's immediate task was to assist the patient in getting to know, and afterwards in overcoming, the resistances which emerged in him during treatment and of which, to begin with, he himself was unaware. And it was found at the same time that the essential part of the process of cure lay in the overcoming of these resistances and that unless this was achieved no permanent mental change could be brought about in the patient. Since the analyst's efforts have in this way been directed upon the patient's resistance, analytic technique has attained a certainty and delicacy rivalling that of surgery. Consequently, everyone is strongly advised against undertaking psycho-analytic treatments without a strict training, and a physician who ventures upon them on the strength of his medical qualification is in no respect better than a layman.

Psycho-Analysis as a Therapeutic Procedure. - Psycho-analysis has never set itself up as a panacea and has never claimed to perform miracles. In one of the most difficult spheres of medical activity it is the only possible method of treatment for certain illnesses and for others it is the method which yields the best or the most permanent results - though never without a corresponding expenditure of time and trouble. A physician who is not wholly absorbed in the work of giving help will find his labours amply repaid by obtaining an unhopd-for insight into the complications of mental life and the interrelations between the mental and the physical. Where at present it cannot offer help but only theoretical understanding, it may perhaps be preparing the way for some later, more direct means of influencing neurotic disorders. Its province is above all the two transference neuroses, hysteria and obsessional neurosis, in which it has contributed to the discovery of their internal structure and operative mechanisms; and, beyond them, all kinds of phobias, inhibitions, deformities of character, sexual perversions and difficulties in erotic life. Some analysts (Jelliffe, Groddeck, Felix Deutsch) have reported too that the analytic treatment of gross organic diseases is not unpromising, since a mental factor not infrequently contributes to the origin and continuance of such illnesses. Since psycho-analysis demands a certain amount of psychical plasticity from its patients, some kind of age-limit must be laid down in their selection; and since it necessitates the devotion of long and intense attention to the individual patient, it would be uneconomical to squander such expenditure upon completely worthless persons who happen to be neurotic. Experience upon material in clinics can alone show what modifications may be necessary in order to make psycho-analytic treatment accessible to wider strata of the population or to adapt it to weaker intelligences.

Comparison between Psycho-Analysis and Hypnotic and Suggestive Methods. - Psycho-analytic procedure differs from all methods making use of suggestion, persuasion, etc., in that it does not seek to suppress by means of authority any mental phenomenon that may occur in the patient. It endeavours to trace the causation of the phenomenon and to remove it by bringing about a permanent modification in the conditions that led to it. In psycho-analysis the suggestive influence which is inevitably exercised by the physician is diverted on to the task assigned to the patient of overcoming his resistances, that is, of carrying forward the curative process. Any danger of falsifying the products of a patient's memory by suggestion can be avoided by prudent handling of the technique; but in general the arousing of resistances is a guarantee against the misleading effects of suggestive influence. It may be laid down that the aim of the treatment is to remove the patient's resistances and to pass his repressions in review and thus to bring about the most far-reaching unification and strengthening of his ego, to enable him to save the mental energy which he is expending upon internal conflicts, to make the best of him that his inherited capacities will allow and so to make him as efficient and as capable of enjoyment as is possible. The removal of the symptoms of the illness is not specifically aimed at, but is achieved, as it were, as a by-product if the analysis is properly carried through. The analyst respects the patient's individuality and does not seek to remould him in accordance with his own - that is, according to the physician's - personal ideals; he is glad to avoid giving advice and instead to arouse the patient's power of initiative.

Its Relation to Psychiatry. - Psychiatry is at present essentially a descriptive and classificatory science whose orientation is still towards the somatic rather than the psychological and which is without the possibility of giving explanations of the phenomena which it observes. Psycho-analysis does not, however, stand in opposition to it, as the almost unanimous behaviour of the psychiatrists might lead one to believe. On the contrary, as a *depth-psychology*, a psychology of those processes in mental life which are withdrawn from consciousness, it is called upon to provide psychiatry with an indispensable groundwork and to free it from its present limitations. We can foresee that the future will give birth to a scientific psychiatry, to which psycho-analysis has served as an introduction.

Criticisms and Misunderstandings of Psycho-Analysis. - Most of what is brought up against psycho-analysis, even in scientific works, is based upon insufficient information which in its turn seems to be determined by emotional resistances. Thus it is a mistake to accuse psycho-analysis of 'pan-sexualism' and to allege that it derives all mental occurrences from sexuality and traces them all back to it. On the contrary, psycho-analysis has from the very first distinguished the sexual instincts from others which it has provisionally termed 'ego instincts'. It has never dreamt of trying to explain 'everything', and even the neuroses it has traced back not to sexuality alone but to the conflict between the sexual impulses and the ego. In psycho-analysis (unlike the works of C. G. Jung) the term '*libido*' does not mean psychical energy in general but the motive force of the sexual instincts. Some assertions, such as that every dream is the fulfilment of a sexual wish, have never been maintained by it at all. The charge of one-sidedness made against psycho-analysis, which, as *the science of the unconscious mind*, has its own definite and restricted field of work, is as inapplicable as it would be if it were made against chemistry. To believe that psycho-analysis seeks a cure for neurotic disorders by giving a free rein to sexuality is a serious misunderstanding which can only be excused by ignorance. The making conscious of repressed sexual desires in analysis makes it possible, on the contrary, to obtain a mastery over them which the previous repression had been unable to achieve. It can more truly be said that analysis sets the neurotic free from the chains of his sexuality. Moreover, it is quite unscientific to judge analysis by whether it is calculated to undermine religion, authority and morals; for, like all sciences, it is entirely non-tendentious and has only a single aim - namely to arrive at a consistent view of one portion of reality. Finally, one can only characterize as simple-minded the fear which is sometimes expressed that all the highest goods of humanity, as they are called - research, art, love, ethical and social sense - will lose their value or their dignity because psycho-analysis is in a position to demonstrate their origin in elementary and animal instinctual impulses.

The Non-Medical Applications and Correlations of Psycho-analysis. - Any estimate of psycho-analysis would be incomplete if it failed to make clear that, alone among the medical disciplines, it has the most extensive relations with the mental sciences, and that it is in a position to play a part of the same importance in the studies of religious and cultural history and in the sciences of mythology and literature as it is in psychiatry. This may seem strange when we reflect that originally its only object was the understanding and improvement of neurotic symptoms. But it is easy to indicate the starting-point of the bridge that leads over to the mental sciences. The analysis of dreams gave us an insight into the unconscious processes of the mind and showed us that the mechanisms which produce pathological symptoms are also operative in the normal mind. Thus psychoanalysis became a *depth-psychology* and capable as such of being applied to the mental sciences, and it was able to answer a good number of questions with which the academic psychology of consciousness was helpless to deal. At quite an early stage problems of human *phyllogenesis* arose. It became clear that pathological function was often nothing more than a *regression* to an earlier stage in the development of normal function. C. G. Jung was the first to draw explicit attention to the striking similarity between the disordered phantasies of sufferers from dementia praecox and the myths of primitive peoples; while the present writer pointed out that the two wishes which combine to form the Oedipus complex coincide precisely with the two principal prohibitions imposed by *totemism* (not to kill the tribal ancestor and not to marry any woman belonging to one's own clan) and drew far-reaching conclusions from this fact. The significance of the Oedipus complex began to grow to gigantic proportions and it looked as though social order, morals, justice and religion had arisen together in the primaeval ages of mankind as reaction-formations against the Oedipus complex. Otto Rank threw a brilliant light upon mythology and the history of literature by the application of psycho-analytic views, as did Theodor Reik upon the history of morals and religions, while Dr. Pfister, of Zurich, aroused the interest of religious and secular teachers and demonstrated the importance of the psycho-analytic standpoint for education. Further discussion of these applications of psycho-analysis would be out of place here, and it is enough to say that the limits of their influence are not yet in sight.

Psycho-analysis an Empirical Science. - Psycho-analysis is not, like philosophies, a system starting out from a few sharply defined basic concepts, seeking to grasp the whole universe with the help of these and, once it is completed, having no room for fresh discoveries or better understanding. On the contrary, it keeps close to the facts in its field of study, seeks to solve the immediate problems of observation, gropes its way forward by the help of experience, is always incomplete and always ready to correct or modify its theories. There is no incongruity (any more than in the case of physics or chemistry) if its most general concepts lack clarity and if its postulates are provisional; it leaves their more precise definition to the results of future work.

(B) THE LIBIDO THEORY

Libido is a term used in the theory of the instincts for describing the dynamic manifestation of sexuality. It was already used in this sense by Moll (1898) and was introduced into psycho-analysis by the present writer. What follows is limited to a description of the developments which the theory of the instincts has passed through in psycho-analysis - developments which are still proceeding.

Contrast between Sexual and Ego Instincts. - Psycho-analysis early became aware that all mental occurrences must be regarded as built on the basis of an interplay of the forces of the elementary instincts. This, however, led to a difficult predicament, since psychology included no theory of the instincts. No one could say what an instinct really was, the question was left entirely to individual caprice, and every psychologist was in the habit of postulating any instincts in any number that he chose. The first sphere of phenomena to be studied by psycho-analysis comprised what are known as the transference neuroses (hysteria and obsessional neurosis). It was found that their symptoms came about by sexual instinctual impulses being rejected (repressed) by the subject's personality (his ego) and then finding expression by circuitous paths through the unconscious. These facts could be met by drawing a contrast between the sexual instincts and ego instincts (*instincts of self-preservation*), which was in line with the popular saying that hunger and love are what make the world go round: libido was the manifestation of the force of love in the same sense as was hunger of the self-preservative instinct. The nature of the ego instincts remained for the time being undefined and, like all the other characteristics of the ego, inaccessible to analysis. There was no means of deciding whether, and if so what, qualitative differences were to be assumed to exist between the two classes of instincts.

Primal Libido. - C. G. Jung attempted to resolve this obscurity along speculative lines by assuming that there was only a single primal libido which could be either sexualized or desexualized and which therefore coincided in its essence with mental energy in general. This innovation was methodologically disputable, caused a great deal of confusion, reduced the term 'libido' to the level of a superfluous synonym and was still in practice confronted with the necessity for distinguishing between sexual and asexual libido. The difference between the sexual instincts and instincts with other aims was not to be got rid of by means of a new definition.

Sublimation. - An attentive examination of the sexual trends, which alone were accessible to psycho-analysis, had meanwhile led to some remarkable detailed findings. What is described as the sexual instinct turns out to be of a highly composite nature and is liable to disintegrate once more into its component instincts. Each component instinct is unalterably characterized by its source, that is, by the region or zone of the body from which its excitation is derived. Each has furthermore as distinguishable features an *object* and an *aim*. The aim is always discharge accompanied by satisfaction, but it is capable of being changed from activity to passivity. The object is less closely attached to the instinct than was at first supposed; it is easily exchanged for another one, and, moreover, an instinct which had an external object can be turned round upon the subject's own self. The separate instincts can either remain independent of one another or - in what is still an inexplicable manner - can be combined and merged into one another to perform work in common. They are also able to replace one another and to transfer their libidinal cathexis to one another, so that the satisfaction of one instinct can take the place of the satisfaction of others. The most important vicissitude which an instinct can undergo seems to be *sublimation*; here both object and aim are changed, so that what was originally a sexual instinct finds satisfaction in some achievement which is no longer sexual but has a higher social or ethical valuation. These different features do not as yet combine to form an integral picture.

Narcissism. - A decisive advance was made when the analysis of dementia praecox and other psychotic disorders was ventured upon and thus the examination was begun of the ego itself, which had so far been known only as the agency of repression and opposition. It was found that the pathogenic process in dementia praecox is the withdrawal of the libido from objects and its introduction into the ego, while the clamorous symptoms of the disease arise from the vain struggles of the libido to find a pathway back to objects. It thus turned out to be possible for object-libido to change into cathexis of the ego and *vice versa*. Further reflection showed that this process must be presumed to occur on the largest scale and that the ego is to be regarded as a great reservoir of libido from which libido is sent out *to* objects and which is always ready to absorb libido flowing back *from* objects. Thus the instincts of self-preservation were also of a libidinal nature: they were sexual instincts which, instead of external objects, had taken the subject's own ego as an object. Clinical experience had made us familiar with people who behaved in a striking fashion as though they were in love with themselves and this perversion had been given the name of *narcissism*. The libido of the self-preservative instincts was now described as *narcissistic libido* and it was recognized that a high degree of this self-love constituted the primary and normal state of things. The earlier formula laid down for the transference neuroses consequently required to be modified, though not corrected. It was better, instead of speaking of a conflict between sexual instincts and ego instincts, to speak of a conflict between object-libido and ego-libido, or, since the nature of these instincts was the same, between the object-cathexes and the ego.

Apparent Approach to Jung's Views. - It thus seemed on the face of it as though the slow process of psycho-analytic research was following in the steps of Jung's speculation about a primal libido, especially because the transformation of object-libido into narcissism necessarily carried along with it a certain degree of desexualization, or abandonment of the specifically sexual aims. Nevertheless, it has to be borne in mind that the fact that the self-preservative instincts of the ego are recognized as libidinal does not necessarily prove that there are no other instincts operating in the ego.

The Herd Instinct. - It has been maintained in many quarters that there is a special innate and not further analysable 'herd instinct', which determines the social behaviour of human beings and impels individuals to come together into larger communities. Psycho-analysis finds itself in contradiction to this view. Even if the social instinct is innate, it may without any difficulty be traced back to what were originally libidinal object-cathexes and may have developed in the childhood of the individual as a reaction-formation against hostile attitudes of rivalry. It is based on a peculiar kind of identification with other people.

Aim-inhibited Sexual Impulses. - The social instincts belong to a class of instinctual impulses which need not be described as sublimated, though they are closely related to these. They have not abandoned their directly sexual aims, but they are held back by internal resistances from attaining them; they rest content with certain approximations to satisfaction and for that very reason lead to especially firm and permanent attachments between human beings. To this class belong in particular the affectionate relations between parents and children, which were originally fully sexual, feelings of friendship, and the emotional ties in marriage which had their origin in sexual attraction.

Recognition of Two Classes of Instincts in Mental Life. - Though psycho-analysis endeavours as a rule to develop its theories as independently as possible from those of other sciences, it is nevertheless obliged to seek a basis for the theory of the instincts in biology. On the ground of a far-reaching consideration of the processes which go to make up life and which lead to death, it becomes probable that we should recognize the existence of two classes of instincts, corresponding to the contrary processes of construction and dissolution in the organism. On this view, the one set of instincts, which work essentially in silence, would be those which follow the aim of leading the living creature to death and therefore deserve to be called the '*death instincts*'; these would be directed outwards as the result of the combination of numbers of unicellular elementary organisms, and would manifest themselves as *destructiveness* or *aggressive* impulses. The other set of instincts would be those which are better known to us in analysis - the libidinal, sexual or life instincts, which are best comprised under the name of *Eros*; their purpose would be to form living substance into ever greater unities, so that life may be prolonged and brought to higher development. The erotic instincts and the death instincts would be present in living beings in regular mixtures or fusions; but 'defusions' would also be liable to occur. Life would consist in the manifestations of the conflict or interaction between the two classes of instincts; death would mean for the individual the victory of the destructive instincts, but reproduction would mean for him the victory of *Eros*.

The Nature of the Instincts. - This view would enable us to characterize instincts as tendencies inherent in living substance towards restoring an earlier state of things: that is to say, they would be historically determined and of a conservative nature and, as it were, the expression of an inertia or elasticity present in what is organic. Both classes of instincts, *Eros* as well as the death instinct, would, on this view, have been in operation and working against each other from the first origin of life.

A NOTE ON THE PREHISTORY OF THE TECHNIQUE OF ANALYSIS (1920)

A recent book by Havelock Ellis (so justly admired for his researches into sexual science, and an eminent critic of psycho-analysis), which bears the title of *The Philosophy of Conflict* (1919), includes an essay on 'Psycho-Analysis in Relation to Sex.' The aim of this essay is to show that the writings of the creator of analysis should be judged not as a piece of scientific work but as an artistic production. We cannot but regard this view as a fresh turn taken by resistance and as a repudiation of analysis, even though it is disguised in a friendly, indeed in too flattering a manner. We are inclined to meet it with a most decided contradiction.

It is not, however, with a view to contradicting him on this point that we are now concerned with Havelock Ellis's essay, but for another reason. His wide reading has enabled him to bring forward an author who practised and recommended free association as a technique, though for purposes other than ours, and thus has a claim to be regarded as a forerunner of psycho-analysis.

'In 1857, Dr. J. J. Garth Wilkinson, more noted as a Swedenborgian mystic and poet than as a physician, published a volume of mystic doggerel verse written by what he considered "a new method", the method of "Impression". "A theme is chosen or written down," he stated; "as soon as this is done the first impression upon the mind which succeeds the act of writing the title is the beginning of the evolution of that theme, no matter how strange or alien the word or phrase may seem." "The first mental movement, the first word that comes" is "the response to the mind's desire for the unfolding of the subject." It is continued by the same method, and Garth Wilkinson adds: "I have always found it lead by an infallible instinct into the subject." The method was, as Garth Wilkinson viewed it, a kind of exalted *laissez-faire*, a command to the deepest unconscious instincts to express themselves. Reason and will, he pointed out, are left aside; you trust to "an influx", and the faculties of the mind are "directed to ends they know not of". Garth Wilkinson, it must be clearly understood, although he was a physician, used this method for religious and literary, and never for scientific or medical ends; but it is easy to see that essentially it is the method of psycho-analysis applied to oneself, and it is further evidence how much Freud's method is an artist's method.'

Those who are familiar with psycho-analytic literature will recall at this point the interesting passage in Schiller's correspondence with Körner¹ in which (1788) the great poet and thinker recommends anyone who desires to be productive to adopt the method of free association. It is to be suspected that what is alleged to be Garth Wilkinson's new technique had already occurred to the minds of many others and that its systematic application in psycho-analysis is not evidence so much of Freud's artistic nature as of his conviction, amounting almost to a prejudice, that all mental events are completely determined. It followed from this view that the first and most likely possibility was that a free association would be related to the subject designated; and this was confirmed by experience in analysis except in so far as too great resistances made the suspected connection unrecognizable.

Meanwhile it is safe to assume that neither Schiller nor Garth Wilkinson had in fact any influence on the choice of psycho-analytic technique. It is from another direction that there are indications of a personal influence at work.

¹ Pointed out by Otto Rank and quoted in my *Interpretation of Dreams* (1900a)

A short time ago in Budapest Dr. Hugo Dubowitz drew Dr. Ferenczi's attention to a short essay covering only four and a half pages, by Ludwig Börne. This was written in 1823 and was reprinted in the first volume of the 1862 edition of his collected works. It is entitled 'The Art of Becoming an Original Writer in Three Days', and shows the familiar stylistic features of Jean Paul, of whom Börne was at that time a great admirer. He ends the essay with the following sentences:

'And here follows the practical application that was promised. Take a few sheets of paper and for three days on end write down, without fabrication or hypocrisy, everything that comes into your head. Write down what you think of yourself, of your wife, of the Turkish War, of Goethe, of Fonk's trial, of the Last Judgement, of your superiors - and when three days have passed you will be quite out of your senses with astonishment at the new and unheard-of thoughts you have had. This is the art of becoming an original writer in three days.'

When Professor Freud came to read this essay of Börne's, he brought forward a number of facts that may have an important bearing on the question that is under discussion here as to the prehistory of the psycho-analytic use of free associations. He said that when he was fourteen he had been given Börne's works as a present, that he still possessed the book now, fifty years later, and that it was the only one that had survived from his boyhood. Börne, he said, had been the first author into whose writings he had penetrated deeply. He could not remember the essay in question, but some of the others that were contained in the same volume - such as 'A Tribute to the Memory of Jean Paul,' 'The Artist in Eating', and 'The Fool at the White Swan Inn' - kept on recurring to his mind for no obvious reason over a long period of years. He was particularly astonished to find expressed in the advice to the original writer some opinions which he himself had always cherished and vindicated. For instance: 'A disgraceful cowardliness in regard to thinking holds us all back. The censorship of governments is less oppressive than the censorship exercised by public opinion over our intellectual productions.' (Moreover there is a reference here to a 'censorship', which reappears in psycho-analysis as the dream-censorship.) 'It is not lack of intellect but lack of character that prevents most writers from being better than they are. . . . Sincerity is the source of all genius, and men would be cleverer if they were more moral. . . .'

Thus it seems not impossible that this hint may have brought to light the fragment of cryptomnesia which in so many cases may be suspected to lie behind apparent originality.

ASSOCIATIONS OF A FOUR-YEAR-OLD CHILD
(1920)

Here is part of a letter from an American mother: 'I must tell you what my little girl said yesterday. I have not yet recovered from my astonishment. Cousin Emily was talking of how she was going to take an apartment. Whereupon the child said: "If Emily gets married, she'll have a baby." I was very much surprised and asked her: "Why, how do you know that?" And she replied: "Well, when anyone gets married, a baby always comes." I repeated: "But how can you tell that?" And the little girl answered: "Oh, I know a lot besides. I know that trees grow in the ground." What a strange association! That is precisely what I intend to say to her one day by way of enlightening her. Then she went on: "And I know that God makes the world." When she talks like this I can scarcely believe that she is not yet four years old.'

The mother herself seems to have understood the transition from the child's first remark to her second one. What she was trying to say was: 'I know that babies grow inside their mother.' She was not expressing this knowledge directly, but symbolically, by replacing the mother by Mother Earth. We have already learnt from numerous incontestable observations the early age at which children know how to make use of symbols. But the little girl's third remark carries on the same context. We can only suppose that she was trying to convey a further piece of her knowledge about the origin of babies: 'I know that it's all the work of the father.' But this time she was replacing the direct thought by the appropriate sublimation - that God makes the world.

DR. ANTON VON FREUND
(1920)

DR. ANTON VON FREUND, who has been General Secretary of the International Psycho-Analytical Association since the Budapest Congress in September 1918, died on January 20, 1920, in a Vienna sanatorium, a few days after completing his fortieth year. He was the most powerful promoter of our science and one of its brightest hopes. Born in Budapest in 1880, he obtained a doctorate in philosophy. He intended to become a teacher, but was persuaded to enter his father's industrial undertaking. But the great successes he attained as a manufacturer and organizer failed to satisfy the two needs which were active in the depths of his nature - for social benefaction and scientific activity. Seeking nothing for himself, and possessing every gift which can charm and captivate, he used his material powers to assist others and to soften the hardness of their destiny as well as to sharpen in all directions the sense of social justice. In this way he acquired a wide circle of friends, who will deeply mourn his loss.

When, during his last years, he came to know psycho-analysis, it seemed to him to promise the fulfilment of his two great wishes. He set himself the task of helping the masses by psycho-analysis and of making use of the therapeutic effects of that medical technique, which had hitherto only been at the service of the rich, in order to mitigate the neurotic suffering of the poor. Since the State took no heed of the neuroses of the common people, since hospital clinics for the most part rejected psycho-analytic therapy without being able to offer any substitute for it, and since the few psycho-analytic physicians, tied by the necessity for maintaining themselves, were unequal to such a gigantic task, Anton von Freund sought, by his private initiative, to open a path for every one towards the fulfilment of this important social duty. During the years of the war he had collected what was then the very considerable sum of one and a half million *kronen* for humanitarian purposes in the city of Budapest. With the concurrence of Dr Stephan von Bárczy, the then Burgomaster, he assigned this sum for the foundation of a psycho-analytic Institute in Budapest, in which analysis was to be practised, taught and made accessible to the people. It was intended to train a considerable number of physicians in this Institute who would then receive an honorarium from it for the treatment of poor neurotics in an out-patient clinic. The Institute, furthermore, was to be a centre for further scientific research in analysis. Dr. Ferenczi was to be the scientific head of the Institute; von Freund himself was to undertake its organization and finances. The founder handed over a relatively smaller sum to Professor Freud for the foundation of an international psycho-analytic publishing house. But,

Was sind Hoffnungen, was sind Entwürfe,
die der Mensch, der vergängliche, baut?

Von Freund's premature death has put an end to these philanthropic schemes, with all their scientific hopes. Though the fund which he collected is still in existence, the attitude of those who are now in power in the Hungarian capital gives no promise that his intentions will be fulfilled. Only the psycho-analytical publishing house has come to birth in Vienna.

None the less, the example which von Freund sought to set has already had its effect. A few weeks after his death, thanks to the energy and liberality of Dr. Max Eitingon, the first psycho-analytical out-patients' clinic has been opened in Berlin. Thus von Freund's work is carried on, though he himself can never be replaced or forgotten.

PREFACE TO J. J. PUTNAM'S *ADDRESSES ON PSYCHO-ANALYSIS*
(1921)

The editor of this series must feel a special satisfaction in being able to issue as its opening volume this collection of the psycho-analytical writings of Professor James J. Putnam, the distinguished neurologist of Harvard University. Professor Putnam, who died in 1918 at the age of seventy-two, was not only the first American to interest himself in psycho-analysis, but soon became its most decided supporter and its most influential representative in America. In consequence of the established reputation which he had gained through his activities as a teacher, as well as through his important work in the domain of organic nervous disease, and thanks to the universal respect which his personality enjoyed, he was able to do perhaps more than anyone for the spread of psycho-analysis in his own country, and was able to protect it from aspersions which, on the other side of the Atlantic no less than this, would inevitably have been cast upon it. But all such reproaches were bound to be silenced when a man of Putnam's lofty ethical standards and moral rectitude had ranged himself among the supporters of the new science and of the therapeutics based upon it.

The papers here collected into a single volume, which were written by Putnam between 1909 and the end of his life, give a good picture of his relations to psycho-analysis. They show how he was at first occupied in correcting a provisional judgement which was based on insufficient knowledge; how he then accepted the essence of analysis, recognized its capacity for throwing a clear light upon the origin of human imperfections and failings, and how he was struck by the prospect of contributing towards the improvement of humanity along analytical lines; how he then became convinced by his own activities as a physician as to the truth of most of the psycho-analytical conclusions and postulates, and then in his turn bore witness to the fact that the physician who makes use of analysis understands far more about the sufferings of his patients and can do far more for them than was possible with the earlier methods of treatment; and finally how he began to extend beyond the limits of analysis, demanding that as a science it should be linked on to a particular philosophical system, and that its practice should be openly associated with a particular set of ethical doctrines.

So it is not to be wondered at that a mind with such pre-eminently ethical and philosophical tendencies as Putnam's should have desired, after he had plunged deep into psycho-analysis, to establish the closest relation between it and the aims which lay nearest his heart. But his enthusiasm, so admirable in a man of his advanced age, did not succeed in carrying others along with him. Younger people remained cooler. It was especially Ferenczi who expressed the opposite view. The decisive reason for the rejection of Putnam's proposals was the doubt as to which of the countless philosophical systems should be accepted, since they all seemed to rest on an equally insecure basis, and since everything had up till then been sacrificed for the sake of the relative certainty of the results of psycho-analysis. It seemed more prudent to wait, and to discover whether a particular attitude towards life might be forced upon us with all the weight of necessity by analytical investigation itself.

It is our duty to express our thanks to the author's widow, Mrs. Putnam, for her assistance with the manuscripts, with the copyrights, and with financial support, without all of which the publication of this volume would have been impossible. No English manuscripts were forthcoming in the case of the papers numbered VI, VII, and X. They have been translated into English by Dr. Katherine Jones from the German text which originated from Putnam himself.

This volume will keep fresh in analytical circles the memory of the friend whose loss we so profoundly deplore. May it be the first of a series of publications which shall serve the end of furthering the understanding and application of psycho-analysis among those who speak the English tongue - an end to which James J. Putnam dedicated the last ten years of his fruitful life.

January 1921

INTRODUCTION TO J. VARENDONCK'S *THE PSYCHOLOGY OF DAY-DREAMS*
(1921)

This present volume of Dr. Varendonck's contains a significant novelty, and will justly arouse the interest of all philosophers, psychologists and psycho-analysts. After an effort lasting for some years the author has succeeded in getting hold of the mode of thought-activity to which one abandons oneself during the state of distraction into which we readily pass before sleep or upon incomplete awakening. He has brought to the consciousness the chains of thought originating in these conditions without the interference of the will; he has written them down, studied their peculiarities and differences with directed conscious thinking, and has made thereby a series of important discoveries which lead to still vaster problems and give rise to the formulation of still more far-reaching questions. Many a point in the psychology of the dream and the defective act finds, thanks to the observations of Dr. Varendonck, a trustworthy settlement.

It is not my intention to give a review of the author's results. I will content myself with pointing to the significance of his work and will permit myself only a remark concerning the terminology which he has adopted. He includes the sort of thought-activity which he has observed in Bleuler's autistic thinking, but calls it, as a rule, *fore-conscious thinking*, according to the custom prevailing in psycho-analysis. However, the autistic thinking of Bleuler does not by any means correspond with the extension and the contents of the fore-conscious, neither can I admit that the name used by Bleuler has been happily chosen. The designation 'fore-conscious' thinking itself as a characteristic appears to me misleading and unsatisfactory. The point in question is that the sort of thought-activity of which the well-known day-dream is an example - complete by itself, developing a situation or an act that is being brought to a close - constitutes the best and until now the only studied example. This day-dreaming does not owe its peculiarities to the circumstances that it proceeds mostly fore-consciously, nor are the forms changed when it is accomplished consciously. From another point of view we know also that even strictly directed reflection may be achieved without the co-operation of consciousness, that is to say, fore-consciously. For that reason I think it is advisable, when establishing a distinction between the different modes of thought-activity, not to utilize the relation to consciousness in the first instance, and to designate the day-dream, as well as the chains of thought studied by Varendonck, as freely wandering or phantastic thinking, in opposition to intentionally directed reflection. At the same time it should be taken into consideration that even phantastic thinking is not invariably in want of an aim and end-representations.

MEDUSA'S HEAD (1940 [1922])

We have not often attempted to interpret individual mythological themes, but an interpretation suggests itself easily in the case of the horrifying decapitated head of Medusa.

To decapitate = to castrate. The terror of Medusa is thus a terror of castration that is linked to the sight of something. Numerous analyses have made us familiar with the occasion for this: it occurs when a boy, who has hitherto been unwilling to believe the threat of castration, catches sight of the female genitals, probably those of an adult, surrounded by hair, and essentially those of his mother.

The hair upon Medusa's head is frequently represented in works of art in the form of snakes, and these once again are derived from the castration complex. It is a remarkable fact that, however frightening they may be in themselves, they nevertheless serve actually as a mitigation of the horror, for they replace the penis, the absence of which is the cause of the horror. This is a confirmation of the technical rule according to which a multiplication of penis symbols signifies castration.

The sight of Medusa's head makes the spectator stiff with terror, turns him to stone. Observe that we have here once again the same origin from the castration complex and the same transformation of affect! For becoming stiff means an erection. Thus in the original situation it offers consolation to the spectator: he is still in possession of a penis, and the stiffening reassures him of the fact.

This symbol of horror is worn upon her dress by the virgin goddess Athene. And rightly so, for thus she becomes a woman who is unapproachable and repels all sexual desires - since she displays the terrifying genitals of the Mother. Since the Greeks were in the main strongly homosexual, it was inevitable that we should find among them a representation of woman as a being who frightens and repels because she is castrated.

If Medusa's head takes the place of a representation of the female genitals, or rather if it isolates their horrifying effects from their pleasure-giving ones, it may be recalled that displaying the genitals is familiar in other connections as an apotropaic act. What arouses horror in oneself will produce the same effect upon the enemy against whom one is seeking to defend oneself. We read in Rabelais of how the Devil took to flight when the woman showed him her vulva.

The erect male organ also has an apotropaic effect, but thanks to another mechanism. To display the penis (or any of its surrogates) is to say: 'I am not afraid of you. I defy you. I have a penis.' Here, then, is another way of intimidating the Evil Spirit.

In order seriously to substantiate this interpretation it would be necessary to investigate the origin of this isolated symbol of horror in Greek mythology as well as parallels to it in other mythologies.

THE EGO AND THE ID (1923)

Intentionally left blank

THE EGO AND THE ID

The present discussions are a further development of some trains of thought which I opened up in *Beyond the Pleasure Principle* (1920g), and to which, as I remarked there, my attitude was one of a kind of benevolent curiosity. In the following pages these thoughts are linked to various facts of analytic observation and an attempt is made to arrive at new conclusions from this conjunction; in the present work, however, there are no fresh borrowings from biology, and on that account it stands closer to psycho-analysis than does *Beyond the Pleasure Principle*. It is more in the nature of a synthesis than of a speculation and seems to have had an ambitious aim in view. I am conscious, however, that it does not go beyond the roughest outline and with that limitation I am perfectly content.

In these pages things are touched on which have not yet been the subject of psycho-analytic consideration, and it has not been possible to avoid trenching upon some theories which have been put forward by non-analysts or by former analysts on their retreat from analysis. I have elsewhere always been ready to acknowledge what I owe to other workers; but in this instance I feel burdened by no such debt of gratitude. If psycho-analysis has not hitherto shown its appreciation of certain things, this has never been because it overlooked their achievement or sought to deny their importance, but because it followed a particular path, which had not yet led so far. And finally, when it has reached them, things have a different look to it from what they have to others.

I

CONSCIOUSNESS AND WHAT IS UNCONSCIOUS

In this introductory chapter there is nothing new to be said and it will not be possible to avoid repeating what has often been said before.

The division of the psychical into what is conscious and what is unconscious is the fundamental premiss of psycho-analysis; and it alone makes it possible for psycho-analysis to understand the pathological processes in mental life, which are as common as they are important, and to find a place for them in the framework of science. To put it once more, in a different way: psycho-analysis cannot situate the essence of the psychical in consciousness, but is obliged to regard consciousness as a quality of the psychical, which may be present in addition to other qualities or may be absent.

If I could suppose that everyone interested in psychology would read this book, I should also be prepared to find that at this point some of my readers would already stop short and would go no further; for here we have the first shibboleth of psycho-analysis. To most people who have been educated in philosophy the idea of anything psychical which is not also conscious is so inconceivable that it seems to them absurd and refutable simply by logic. I believe this is only because they have never studied the relevant phenomena of hypnosis and dreams, which - quite apart from pathological manifestations - necessitate this view. Their psychology of consciousness is incapable of solving the problems of dreams and hypnosis.

'Being conscious' is in the first place a purely descriptive term, resting on perception of the most immediate and certain character. Experience goes on to show that a psychical element (for instance, an idea) is not as a rule conscious for a protracted length of time. On the contrary, a state of consciousness is characteristically very transitory; an idea that is conscious now is no longer so a moment later, although it can become so again under certain conditions that are easily brought about. In the interval the idea was - we do not know what. We can say that it was *latent*, and by this we mean that it was *capable of becoming conscious* at any time. Or, if we say that it was *unconscious*, we shall also be giving a correct description of it. Here 'unconscious' coincides with 'latent and capable of becoming conscious'. The philosophers would no doubt object: 'No, the term "unconscious" is not applicable here; so long as the idea was in a state of latency it was not anything psychical at all.' To contradict them at this point would lead to nothing more profitable than a verbal dispute.

But we have arrived at the term or concept of the unconscious along another path, by considering certain experiences in which mental *dynamics* play a part. We have found - that is, we have been obliged to assume - that very powerful mental processes or ideas exist (and here a quantitative or *economic* factor comes into question for the first time) which can produce all the effects in mental life that ordinary ideas do (including effects that can in their turn become conscious as ideas), though they themselves do not become conscious. It is unnecessary to repeat in detail here what has been explained so often before. It is enough to say that at this point psycho-analytic theory steps in and asserts that the reason why such ideas cannot become conscious is that a certain force opposes them, that otherwise they could become conscious, and that it would then be apparent how little they differ from other elements which are admittedly psychical. The fact that in the technique of psycho-analysis a means has been found by which the opposing force can be removed and the ideas in question made conscious renders this theory irrefutable. The state in which the ideas existed before being made conscious is called by us *repression*, and we assert that the force which instituted the repression and maintains it is perceived as *resistance* during the work of analysis

Thus we obtain our concept of the unconscious from the theory of repression. The repressed is the prototype of the unconscious for us. We see, however, that we have two kinds of unconscious - the one which is latent but capable of becoming conscious, and the one which is repressed and which is not, in itself and without more ado, capable of becoming conscious. This piece of insight into psychical dynamics cannot fail to affect terminology and description. The latent, which is unconscious only descriptively, not in the dynamic sense, we call *preconscious*; we restrict the term *unconscious* to the dynamically unconscious repressed; so that now we have three terms, conscious (*Cs.*), *preconscious* (*Pcs.*), and unconscious (*Ucs.*), whose sense is no longer purely descriptive. The *Pcs.* is presumably a great deal closer to the *Cs.* than is the *Ucs.*, and since we have called the *Ucs.* psychical we shall with even less hesitation call the latent *Pcs.* psychical. But why do we not rather, instead of this, remain in agreement with the philosophers and, in a consistent way, distinguish the *Pcs.* as well as the *Ucs.* from the conscious psychical? The philosophers would then propose that the *Pcs.* and the *Ucs.* should be described as two species or stages of the 'psychoid', and harmony would be established. But end less difficulties in exposition would follow; and the one important fact, that these two kinds of 'psychoid' coincide in almost every other respect with what is admittedly psychical, would be forced into the background in the interests of a prejudice dating from a period in which these psychoids, or the most important part of them, were still unknown.

We can now play about comfortably with our three terms, *Cs.*, *Pcs.*, and *Ucs.*, so long as we do not forget that in the descriptive sense there are two kinds of unconscious, but in the dynamic sense only one. For purposes of exposition this distinction can in some cases be ignored, but in others it is of course indispensable. At the same time, we have become more or less accustomed to this ambiguity of the unconscious and have managed pretty well with it. As far as I can see, it is impossible to avoid this ambiguity; the distinction between conscious and unconscious is in the last resort a question of perception, which must be answered 'yes' or 'no', and the act of perception itself tells us nothing of the reason why a thing is or is not perceived. No one has a right to complain because the actual phenomenon expresses the dynamic factor ambiguously.¹

¹ This may be compared so far with my 'Note on the Unconscious in Psycho-Analysis' (1912g). A new turn taken by criticisms of the unconscious deserves consideration at this point. Some investigators, who do not refuse to recognize the facts of psycho-analysis but who are unwilling to accept the unconscious, find a way out of the difficulty in the fact, which no one contests, that in consciousness (regarded as a phenomenon) it is possible to distinguish a great variety of gradations in intensity or clarity. Just as there are processes which are very vividly, glaringly, and tangibly conscious, so we also experience others which are only faintly, hardly even noticeably conscious; those that are most faintly conscious are, it is argued, the ones to which psycho-analysis wishes to apply the unsuitable name 'unconscious'. These too, however (the argument proceeds), are conscious or 'in consciousness', and can be made fully and intensely conscious if sufficient attention is paid to them.

In so far as it is possible to influence by arguments the decision of a question of this kind which depends either on convention or on emotional factors, we may make the following comments. The reference to gradations of clarity in consciousness is in no way conclusive and has no more evidential value than such analogous statements as: 'There are so very many gradations in illumination - from the most glaring and dazzling light to the dimmest glimmer - therefore there is no such thing as darkness at all'; or, 'There are varying degrees of vitality, therefore there is no such thing as death.' Such statements may in a certain way have a meaning, but for practical purposes they are worthless. This will be seen if one tries to draw particular conclusions from them, such as, 'there is therefore no need to strike a light', or, 'therefore all organisms are immortal'. Further, to include 'what is unnoticeable' under the concept of 'what is conscious' is simply to play havoc with the one and only piece of direct and certain knowledge that we have about the mind. And after all, a consciousness of which one knows nothing seems to me a good deal more absurd than something mental that is unconscious. Finally, this attempt to equate what is unnoticed with what is unconscious is obviously made without taking into account the dynamic conditions involved, which were the decisive factors in forming the psycho-analytic view. For it ignores two facts: first, that it is exceedingly difficult and requires very great effort to concentrate enough attention on something unnoticed of this kind; and secondly, that when this has been achieved the thought which was previously unnoticed is not recognized by consciousness, but often seems entirely alien and opposed to it and is promptly disavowed by it. Thus, seeking refuge from the unconscious in what is scarcely noticed or unnoticed is after all only a derivative of the preconceived belief which regards the identity of the psychical and the conscious as settled once and for all.

In the further course of psycho-analytic work, however, even these distinctions have proved to be inadequate and, for practical purposes, insufficient. This has become clear in more ways than one; but the decisive instance is as follows. We have formed the idea that in each individual there is a coherent organization of mental processes; and we call this his *ego*. It is to this ego that consciousness is attached; the ego controls the approaches to motility - that is, to the discharge of excitations into the external world; it is the mental agency which supervises all its own constituent processes, and which goes to sleep at night, though even then it exercises the censorship on dreams. From this ego proceed the repressions, too, by means of which it is sought to exclude certain trends in the mind not merely from consciousness but also from other forms of effectiveness and activity. In analysis these trends which have been shut out stand in opposition to the ego, and the analysis is faced with the task of removing the resistances which the ego displays against concerning itself with the repressed. Now we find during analysis that, when we put certain tasks before the patient, he gets into difficulties; his associations fail when they should be coming near the repressed. We then tell him that he is dominated by a resistance; but he is quite unaware of the fact, and, even if he guesses from his unpleasurable feelings that a resistance is now at work in him, he does not know what it is or how to describe it. Since, however, there can be no question but that this resistance emanates from his ego and belongs to it, we find ourselves in an unforeseen situation. We have come upon something in the ego itself which is also unconscious, which behaves exactly like the repressed - that is, which produces powerful effects without itself being conscious and which requires special work before it can be made conscious. From the point of view of analytic practice, the consequence of this discovery is that we land in endless obscurities and difficulties if we keep to our habitual forms of expression and try, for instance, to derive neuroses from a conflict between the conscious and the unconscious. We shall have to substitute for this antithesis another, taken from our insight into the structural conditions of the mind - the antithesis between the coherent ego and the repressed which is split off from it.¹

¹ Cf. *Beyond the Pleasure Principle* (1920g).

For our conception of the unconscious, however, the consequences of our discovery are even more important. Dynamic considerations caused us to make our first correction; our insight into the structure of the mind leads to the second. We recognize that the *Ucs.* does not coincide with the repressed; it is still true that all that is repressed is *Ucs.*, but not all that is *Ucs.* is repressed. A part of the ego, too - and Heaven knows how important a part - may be *Ucs.*, undoubtedly is *Ucs.* And this *Ucs.* belonging to the ego is not latent like the *Pcs.*; for if it were, it could not be activated without becoming *Cs.*, and the process of making it conscious would not encounter such great difficulties. When we find ourselves thus confronted by the necessity of postulating a third *Ucs.*, which is not repressed, we must admit that the characteristic of being unconscious begins to lose significance for us. It becomes a quality which can have many meanings, a quality which we are unable to make, as we should have hoped to do, the basis of far-reaching and inevitable conclusions. Nevertheless we must beware of ignoring this characteristic, for the property of being conscious or not is in the last resort our one beacon-light in the darkness of depth-psychology.

II

THE EGO AND THE ID

Pathological research has directed our interest too exclusively to the repressed. We should like to learn more about the ego, now that we know that it, too, can be unconscious in the proper sense of the word. Hitherto the only guide we have had during our investigations has been the distinguishing mark of being conscious or unconscious; we have finally come to see how ambiguous this can be.

Now all our knowledge is invariably bound up with consciousness. We can come to know even the *Ucs*, only by making it conscious. But stop, how is that possible? What does it mean when we say 'making something conscious'? How can that come about?

We already know the point from which we have to start in this connection. We have said that consciousness is the *surface* of the mental apparatus; that is, we have ascribed it as a function to a system which is spatially the first one reached from the external world - and spatially not only in the functional sense but, on this occasion, also in the sense of anatomical dissection.¹ Our investigations too must take this perceiving surface as a starting-point.

All perceptions which are received from without (sense-perceptions) and from within - what we call sensations and feelings - are *Cs.* from the start. But what about those internal processes which we may - roughly and inexactly - sum up under the name of thought-processes? They represent displacements of mental energy which are effected somewhere in the interior of the apparatus as this energy proceeds on its way towards action. Do they advance to the surface, which causes consciousness to be generated? Or does consciousness make its way to them? This is clearly one of the difficulties that arise when one begins to take the spatial or 'topographical' idea of mental life seriously. Both these possibilities are equally unimaginable, there must be a third alternative.

¹ *Beyond the Pleasure Principle.*

I have already, in another place,¹ suggested that the real difference between a *Ucs.* and a *Pcs.* idea (thought) consists in this: that the former is carried out on some material which remains unknown, whereas the latter (the *Pcs.*) is in addition brought into connection with word-presentations. This is the first attempt to indicate distinguishing marks for the two systems, the *Pcs.* and the *Ucs.*, other than their relation to consciousness. The question, 'How does a thing become conscious?' would thus be more advantageously stated: 'How does a thing become preconscious?' And the answer would be: 'Through becoming connected with the word-presentations corresponding to it.'

These word-presentations are residues of memories; they were at one time perceptions, and like all mnemic residues they can become conscious again. Before we concern ourselves further with their nature, it dawns upon us like a new discovery that only something which has once been a *Cs.* perception can become conscious, and that anything arising from within (apart from feelings) that seeks to become conscious must try to transform itself into external perceptions: this becomes possible by means of memory-traces.

We think of the mnemic residues as being contained in systems which are directly adjacent to the system *Pcpt.-Cs.*, so that the cathexes of those residues can readily extend from within on to the elements of the latter system. We immediately think here of hallucinations, and of the fact that the most vivid memory is always distinguishable both from a hallucination and from an external perception; but it will also occur to us at once that when a memory is revived the cathexis remains in the mnemic system, whereas a hallucination, which is not distinguishable from a perception, can arise when the cathexis does not merely spread over from the memory-trace on to the *Pcpt.* element, but passes over to it *entirely*.

¹ 'The Unconscious'.

Verbal residues are derived primarily from auditory perceptions, so that the system *Pcs.* has, as it were, a special sensory source. The visual components of word-presentations are secondary, acquired through reading, and may to begin with be left on one side; so may the motor images of words, which, except with deaf-mutes, play the part of auxiliary indications. In essence a word is after all the mnemonic residue of a word that has been heard.

We must not be led, in the interests of simplification perhaps, to forget the importance of optical mnemonic residues, when they are of *things*, or to deny that it is possible for thought-processes to become conscious through a reversion to visual residues, and that in many people this seems to be the favoured method. The study of dreams and of preconscious phantasies as shown in Varendonck's observations can give us an idea of the special character of this visual thinking. We learn that what becomes conscious in it is as a rule only the concrete subject-matter of the thought, and that the relations between the various elements of this subject-matter, which is what specially characterizes thoughts, cannot be given visual expression. Thinking in pictures is, therefore, only a very incomplete form of becoming conscious. In some way, too, it stands nearer to unconscious processes than does thinking in words, and it is unquestionably older than the latter both ontogenetically and phylogenetically.

To return to our argument: if, therefore, this is the way in which something that is in itself unconscious becomes preconscious, the question how we make something that is repressed (pre)conscious would be answered as follows. It is done by supplying *Pcs.* intermediate links through the work of analysis. Consciousness remains where it is, therefore; but, on the other hand, the *Ucs.* does not rise into the *Cs.*

Whereas the relation of *external* perceptions to the ego is quite perspicuous, that of *internal* perceptions to the ego requires special investigation. It gives rise once more to a doubt whether we are really right in referring the whole of consciousness to the single superficial system *Pcpt-Cs.*

Internal perceptions yield sensations of processes arising in the most diverse and certainly also in the deepest strata of the mental apparatus. Very little is known about these sensations and feelings; those belonging to the pleasure-unpleasure series may still be regarded as the best examples of them. They are more primordial, more elementary, than perceptions arising externally and they can come about even when consciousness is clouded. I have elsewhere expressed my views about their greater economic significance and the metapsychological reasons for this. These sensations are multilocular, like external perceptions; they may come from different places simultaneously and may thus have different or even opposite qualities.

Sensations of a pleasurable nature have not anything inherently impelling about them, whereas unpleasurable ones have it in the highest degree. The latter impel towards change, towards discharge, and that is why we interpret unpleasure as implying a heightening and pleasure a lowering of energetic cathexis. Let us call what becomes conscious as pleasure and unpleasure a quantitative and qualitative 'something' in the course of mental events; the question then is whether this 'something' can become conscious in the place where it is, or whether it must first be transmitted to the system *Pcpt.*

Clinical experience decides for the latter. It shows us that this 'something' behaves like a repressed impulse. It can exert driving force without the ego noticing the compulsion. Not until there is resistance to the compulsion, a hold-up in the discharge-reaction, does the 'something' at once become conscious as unpleasure. In the same way that tensions arising from physical needs can remain unconscious, so also can pain - a thing intermediate between external and internal perception, which behaves like an internal perception even when its source is in the external world. It remains true, therefore, that sensations and feelings, too, only become conscious through reaching the system *Pcpt.*; if the way forward is barred, they do not come into being as sensations, although the 'something' that corresponds to them in the course of excitation is the same as if they did. We then come to speak, in a condensed and not entirely correct manner, of 'unconscious feelings', keeping up an analogy with unconscious ideas which is not altogether justifiable. Actually the difference is that, whereas with *Ucs ideas* connecting links must be created before they can be brought into the *Cs.*, with *feelings*, which are themselves transmitted directly, this does not occur. In other words: the distinction between *Cs.* and *Pcs.* has no meaning where feelings are concerned; the *Pcs.* here drops out - and feelings are either conscious or unconscious. Even when they are attached to word-presentations, their becoming conscious is not due to that circumstance, but they become so directly.

The part played by word-presentations now becomes perfectly clear. By their interposition internal thought-processes are made into perceptions. It is like a demonstration of the theorem that all knowledge has its origin in external perception. When a hypercathexis of the process of thinking takes place, thoughts are *actually* perceived - as if they came from without and are consequently held to be true.

After this clarifying of the relations between external and internal perception and the superficial system *Pcpt.-Cs.*, we can go on to work out our idea of the ego. It starts out, as we see, from the system *Pcpt.*, which is its nucleus, and begins by embracing the *Pcs.*, which is adjacent to the mnemic residues. But, as we have learnt, the ego is also unconscious.

Now I think we shall gain a great deal by following the suggestion of a writer who, from personal motives, vainly asserts that he has nothing to do with the rigours of pure science. I am speaking of Georg Groddeck, who is never tired of insisting that what we call our ego behaves essentially passively in life, and that, as he expresses it, we are 'lived' by unknown and uncontrollable forces.¹ We have all had impressions of the same kind, even though they may not have overwhelmed us to the exclusion of all others, and we need feel no hesitation in finding a place for Groddeck's discovery in the structure of science. I propose to take it into account by calling the entity which starts out from the system *Pcpt.* and begins by being *Pcs.* the 'ego', and by following Groddeck in calling the other part of the mind, into which this entity extends and which behaves as though it were *Ucs.*, the 'id'.²

¹ Groddeck (1923)

² Groddeck himself no doubt followed the example of Nietzsche, who habitually used this grammatical term for whatever in our nature is impersonal and, so to speak, subject to natural law.

We shall soon see whether we can derive any advantage from this view for purposes either of description or of understanding. We shall now look upon an individual as a psychical id, unknown and unconscious, upon whose surface rests the ego, developed from its nucleus the *Pcpt.* system. If we make an effort to represent this pictorially, we may add that the ego does not completely envelop the id, but only does so to the extent to which the system *Pcpt.* forms its surface, more or less as the germinal disc rests upon the ovum. The ego is not sharply separated from the id; its lower portion merges into it.

But the repressed merges into the id as well, and is merely a part of it. The repressed is only cut off sharply from the ego by the resistances of repression; it can communicate with the ego through the id. We at once realize that almost all the lines of demarcation we have drawn at the instigation of pathology relate only to the superficial strata of the mental apparatus - the only ones known to us. The state of things which we have been describing can be represented diagrammatically (Fig. 1); though it must be remarked that the form chosen has no pre tensions to any special applicability, but is merely intended to serve for purposes of exposition.

Fig. 1.

We might add, perhaps, that the ego wears a 'cap of hearing' - on one side only, as we learn from cerebral anatomy. It might be said to wear it awry.

It is easy to see that the ego is that part of the id which has been modified by the direct influence of the external world through the medium of the *Pcpt.*-Cs.; in a sense it is an extension of the surface-differentiation. Moreover, the ego seems to bring the influence of the external world to bear upon the id and its tendencies, and endeavours to substitute the reality principle for the pleasure principle which reigns unrestrictedly in the id. For the ego, perception plays the part which in the id falls to instinct. The ego represents what may be called reason and common sense, in contrast to the id, which contains the passions. All this falls into line with popular distinctions which we are all familiar with; at the same time, however, it is only to be regarded as holding good on the average or 'ideally'.

The functional importance of the ego is manifested in the fact that normally control over the approaches to motility devolves upon it. Thus in its relation to the id it is like a man on horse back, who has to hold in check the superior strength of the horse; with this difference, that the rider tries to do so with his own strength while the ego uses borrowed forces. The analogy may be carried a little further. Often a rider, if he is not to be parted from his horse, is obliged to guide it where it wants to go; so in the same way the ego is in the habit of transforming the id's will into action as if it were its own.

Another factor, besides the influence of the system *Pcpt.*, seems to have played a part in bringing about the formation of the ego and its differentiation from the id. A person's own body, and above all its surface, is a place from which both external and internal perceptions may spring. It is seen like any other object, but to the *touch* it yields two kinds of sensations, one of which may be equivalent to an internal perception. Psycho-physiology has fully discussed the manner in which a person's own body attains its special position among other objects in the world of perception. Pain, too, seems to play a part in the process, and the way in which we gain new knowledge of our organs during painful illnesses is perhaps a model of the way by which in general we arrive at the idea of our body.

The ego is first and foremost a bodily ego; it is not merely a surface entity, but is itself the projection of a surface. If we wish to find an anatomical analogy for it we can best identify it with the 'cortical homunculus' of the anatomists, which stands on its head in the cortex, sticks up its heels, faces backwards and, as we know, has its speech-area on the left-hand side.

The relation of the ego to consciousness has been entered into repeatedly; yet there are some important facts in this connection which remain to be described here. Accustomed as we are to taking our social or ethical scale of values along with us wherever we go, we feel no surprise at hearing that the scene of the activities of the lower passions is in the unconscious; we expect, moreover, that the higher any mental function ranks in our scale of values the more easily it will find access to consciousness assured to it. Here, however, psycho-analytic experience disappoints us. On the one hand, we have evidence that even subtle and difficult intellectual operations which ordinarily require strenuous reflection can equally be carried out preconsciously and without coming into consciousness. Instances of this are quite incontestable; they may occur, for example, during the state of sleep, as is shown when someone finds, immediately after waking, that he knows the solution to a difficult mathematical or other problem with which he had been wrestling in vain the day before.¹

¹ I was quite recently told an instance of this which was, in fact, brought up as an objection against my description of the 'dream-work'.

There is another phenomenon, however, which is far stranger. In our analyses we discover that there are people in whom the faculties of self-criticism and conscience - mental activities, that is, that rank as extremely high ones - are unconscious and unconsciously produce effects of the greatest importance; the example of resistance remaining unconscious during analysis is therefore by no means unique. But this new discovery, which compels us, in spite of our better critical judgement, to speak of an 'unconscious sense of guilt', bewilders us far more than the other and sets us fresh problems, especially when we gradually come to see that in a great number of neuroses an unconscious sense of guilt of this kind plays a decisive economic part and puts the most powerful obstacles in the way of recovery. If we come back once more to our scale of values, we shall have to say that not only what is lowest but also what is highest in the ego can be unconscious. It is as if we were thus supplied with a proof of what we have just asserted of the conscious ego: that it is first and foremost a body-ego.

III

THE EGO AND THE SUPER-EGO (EGO IDEAL)

If the ego were merely the part of the id modified by the influence of the perceptual system, the representative in the mind of the real external world, we should have a simple state of things to deal with. But there is a further complication.

The considerations that led us to assume the existence of a grade in the ego, a differentiation within the ego, which may be called the 'ego ideal' or 'super-ego', have been stated elsewhere.¹ They still hold good.² The fact that this part of the ego is less firmly connected with consciousness is the novelty which calls for explanation.

At this point we must widen our range a little. We succeeded in explaining the painful disorder of melancholia by supposing that an object which was lost has been set up again inside the ego - that is, that an object-cathexis has been replaced by an identification.³ At that time, however, we did not appreciate the full significance of this process and did not know how common and how typical it is. Since then we have come to understand that this kind of substitution has a great share in determining the form taken by the ego and that it makes an essential contribution towards building up what is called its 'character'.

¹ Cf. 'On Narcissism: an Introduction' (1914c), and *Group Psychology and the Analysis of the Ego* (1921c).

² Except that I seem to have been mistaken in ascribing the function of 'reality-testing' to this super-ego - a point which needs correction. It would fit in perfectly with the relations of the ego to the world of perception if reality-testing remained a task of the ego itself. Some earlier suggestions about a 'nucleus of the ego', never very definitely formulated, also require to be put right, since the system *Pcpt.-Cs.* alone can be regarded as the nucleus of the ego.

³ *Mourning and Melancholia* (1917e).

At the very beginning, in the individual's primitive oral phase, object-cathexis and identification are no doubt indistinguishable from each other. We can only suppose that later on object-cathexes proceed from the id, which feels erotic trends as needs. The ego, which to begin with is still feeble, becomes aware of the object-cathexes, and either acquiesces in them or tries to fend them off by the process of repression.¹

When it happens that a person has to give up a sexual object, there quite often ensues an alteration of his ego which can only be described as a setting up of the object inside the ego, as it occurs in melancholia; the exact nature of this substitution is as yet unknown to us. It may be that by this introjection, which is a kind of regression to the mechanism of the oral phase, the ego makes it easier for the object to be given up or renders that process possible. It may be that this identification is the sole condition under which the id can give up its objects. At any rate the process, especially in the early phases of development, is a very frequent one, and it makes it possible to suppose that the character of the ego is a precipitate of abandoned object-cathexes and that it contains the history of those object-choices. It must, of course, be admitted from the outset that there are varying degrees of capacity for resistance, which decide the extent to which a person's character fends off or accepts the influences of the history of his erotic object-choices. In women who have had many experiences in love there seems to be no difficulty in finding vestiges of their object-cathexes in the traits of their character. We must also take into consideration cases of simultaneous object-cathexis and identification - cases, that is, in which the alteration in character occurs before the object has been given up. In such cases the alteration in character has been able to survive the object-relation and in a certain sense to conserve it.

¹ An interesting parallel to the replacement of object-choice by identification is to be found in the belief of primitive peoples, and in the prohibitions based upon it, that the attributes of animals which are incorporated as nourishment persist as part of the character of those who eat them. As is well known, this belief is one of the roots of cannibalism and its effects have continued through the series of usages of the totem meal down to Holy Communion. The consequences ascribed by this belief to oral mastery of the object do in fact follow in the case of the later sexual object-choice.

From another point of view it may be said that this transformation of an erotic object-choice into an alteration of the ego is also a method by which the ego can obtain control over the id and deepen its relations with it - at the cost, it is true, of acquiescing to a large extent in the id's experiences. When the ego assumes the features of the object, it is forcing itself, so to speak, upon the id as a love-object and is trying to make good the id's loss by saying: 'Look, you can love me too - I am so like the object.'

The transformation of object-libido into narcissistic libido which thus takes place obviously implies an abandonment of sexual aims, a desexualization - a kind of sublimation, therefore. Indeed, the question arises, and deserves careful consideration, whether this is not the universal road to sublimation, whether all sublimation does not take place though the mediation of the ego, which begins by changing sexual object-libido into narcissistic libido and then, perhaps, goes on to give it another aim.¹ We shall later on have to consider whether other instinctual vicissitudes may not also result from this transformation, whether, for instance, it may not bring about a defusion of the various instincts that are fused together.

Although it is a digression from our aim, we cannot avoid giving our attention for a moment longer to the ego's object-identifications. If they obtain the upper hand and become too numerous, unduly powerful and incompatible with one another, a pathological outcome will not be far off. It may come to a disruption of the ego in consequence of the different identifications becoming cut off from one another by resistances; perhaps the secret of the cases of what is described as 'multiple personality' is that the different identifications seize hold of consciousness in turn. Even when things do not go so far as this, there remains the question of conflicts between the various identifications into which the ego comes apart, conflicts which cannot after all be described as entirely pathological.

¹ Now that we have distinguished between the ego and the id, we must recognize the id as the great reservoir of libido indicated in my paper on narcissism (1914c). The libido which flows into the ego owing to the identifications described above brings about its 'secondary narcissism'.

But, whatever the character's later capacity for resisting the influences of abandoned object-cathexes may turn out to be, the effects of the first identifications made in earliest childhood will be general and lasting. This leads us back to the origin of the ego ideal; for behind it there lies hidden an individual's first and most important identification, his identification with the father in his own personal prehistory.¹ This is apparently not in the first instance the consequence or outcome of an object-cathexis; it is a direct and immediate identification and takes place earlier than any object-cathexis. But the object-choices belonging to the first sexual period and relating to the father and mother seem normally to find their outcome in an identification of this kind, and would thus reinforce the primary one.

The whole subject, however, is so complicated that it will be necessary to go into it in greater detail. The intricacy of the problem is due to two factors: the triangular character of the Oedipus situation and the constitutional bisexuality of each individual.

In its simplified form the case of a male child may be described as follows. At a very early age the little boy develops an object-cathexis for his mother, which originally related to the mother's breast and is the prototype of an object-choice on the anaclitic model; the boy deals with his father by identifying himself with him. For a time these two relationships proceed side by side, until the boy's sexual wishes in regard to his mother become more intense and his father is perceived as an obstacle to them; from this the Oedipus complex originates.² His identification with his father then takes on a hostile colouring and changes into a wish to get rid of his father in order to take his place with his mother. Henceforward his relation to his father is ambivalent; it seems as if the ambivalence inherent in the identification from the beginning had become manifest. An ambivalent attitude to his father and an object-relation of a solely affectionate kind to his mother make up the content of the simple positive Oedipus complex in a boy.

¹ Perhaps it would be safer to say 'with the parents'; for before a child has arrived at definite knowledge of the difference between the sexes, the lack of a penis, it does not distinguish in value between its father and its mother. I recently came across the instance of a young married woman whose story showed that, after noticing the lack of a penis in herself, she had supposed it to be absent not in all women, but only in those whom she regarded as inferior, and had still supposed that her mother possessed one. In order to simplify my presentation I shall discuss only identification with the father.

² Cf. *Group Psychology* (1921 c), loc. cit.

Along with the demolition of the Oedipus complex, the boy's object-cathexis of his mother must be given up. Its place may be filled by one of two things: either an identification with his mother or an intensification of his identification with his father. We are accustomed to regard the latter outcome as the more normal; it permits the affectionate relation to the mother to be in a measure retained. In this way the dissolution of the Oedipus complex would consolidate the masculinity in a boy's character. In a precisely analogous way, the outcome of the Oedipus attitude in a little girl may be an intensification of her identification with her mother (or the setting up of such an identification for the first time) - a result which will fix the child's feminine character.

These identifications are not what we should have expected, since they do not introduce the abandoned object into the ego; but this alternative outcome may also occur, and is easier to observe in girls than in boys. Analysis very often shows that a little girl, after she has had to relinquish her father as a love-object, will bring her masculinity into prominence and identify herself with her father (that is, with the object which has been lost), instead of with her mother. This will clearly depend on whether the masculinity in her disposition - whatever that may consist in - is strong enough.

It would appear, therefore, that in both sexes the relative strength of the masculine and feminine sexual dispositions is what determines whether the outcome of the Oedipus situation shall be an identification with the father or with the mother. This is one of the ways in which bisexuality takes a hand in the subsequent vicissitudes of the Oedipus complex. The other way is even more important. For one gets an impression that the simple Oedipus complex is by no means its commonest form, but rather represents a simplification or schematization which, to be sure, is often enough justified for practical purposes. Closer study usually discloses the more complete Oedipus complex, which is twofold, positive and negative, and is due to the bisexuality originally present in children: that is to say, a boy has not merely an ambivalent attitude towards his father and an affectionate object-choice towards his mother, but at the same time he also behaves like a girl and displays an affectionate feminine attitude to his father and a corresponding jealousy and hostility towards his mother. It is this complicating element introduced by bisexuality that makes it so difficult to obtain a clear view of the facts in connection with the earliest object-choices and identifications, and still more difficult to describe them intelligibly. It may even be that the ambivalence displayed in the relations to the parents should be attributed entirely to bisexuality and that it is not, as I have represented above, developed out of identification in consequence of rivalry.

In my opinion it is advisable in general, and quite especially where neurotics are concerned, to assume the existence of the complete Oedipus complex. Analytic experience then shows that in a number of cases one or the other constituent disappears, except for barely distinguishable traces; so that the result is a series with the normal positive Oedipus complex at one end and the inverted negative one at the other, while its intermediate members exhibit the complete form with one or other of its two components preponderating. At the dissolution of the Oedipus complex the four trends of which it consists will group themselves in such a way as to produce a father-identification and a mother-identification. The father-identification will preserve the object-relation to the mother which belonged to the positive complex and will at the same time replace the object-relation to the father which belonged to the inverted complex: and the same will be true, *mutatis mutandis*, of the mother-identification. The relative intensity of the two identifications in any individual will reflect the preponderance in him of one or other of the two sexual dispositions.

The broad general outcome of the sexual phase dominated by the Oedipus complex may, therefore, be taken to be the forming of a precipitate in the ego, consisting of these two identifications in some way united with each other. This modification of the ego retains its special position; it confronts the other contents of the ego as an ego ideal or super-ego.

The super-ego is, however, not simply a residue of the earliest object-choices of the id; it also represents an energetic reaction-formation against those choices. Its relation to the ego is not exhausted by the precept: 'You *ought to be* like this (like your father).' It also comprises the prohibition: 'You *may not be* like this (like your father) - that is, you may not do all that he does; some things are his prerogative.' This double aspect of the ego ideal derives from the fact that the ego ideal had the task of repressing the Oedipus complex; indeed, it is to that revolutionary event that it owes its existence. Clearly the repression of the Oedipus complex was no easy task. The child's parents, and especially his father, were perceived as the obstacle to a realization of his Oedipus wishes; so his infantile ego fortified itself for the carrying out of the repression by erecting this same obstacle within itself. It borrowed strength to do this, so to speak, from the father, and this loan was an extraordinarily momentous act. The super-ego retains the character of the father, while the more powerful the Oedipus complex was and the more rapidly it succumbed to repression (under the influence of authority, religious teaching, schooling and reading), the stricter will be the domination of the super-ego over the ego later on - in the form of conscience or perhaps of an unconscious sense of guilt. I shall presently bring forward a suggestion about the source of its power to dominate in this way - the source, that is, of its compulsive character which manifests itself in the form of a categorical imperative.

If we consider once more the origin of the super-ego as we have described it, we shall recognize that it is the outcome of two highly important factors, one of a biological and the other of a historical nature: namely, the lengthy duration in man of his childhood helplessness and dependence, and the fact of his Oedipus complex, the repression of which we have shown to be connected with the interruption of libidinal development by the latency period and so with the diphasic onset of man's sexual life. According to one psycho-analytic hypothesis, the last-mentioned phenomenon, which seems to be peculiar to man, is a heritage of the cultural development necessitated by the glacial epoch. We see, then, that the differentiation of the super-ego from the ego is no matter of chance; it represents the most important characteristics of the development both of the individual and of the species; indeed, by giving permanent expression to the influence of the parents it perpetuates the existence of the factors to which it owes its origin.

Psycho-analysis has been reproached time after time with ignoring the higher, moral, supra-personal side of human nature. The reproach is doubly unjust, both historically and methodologically. For, in the first place, we have from the very beginning attributed the function of instigating repression to the moral and aesthetic trends in the ego, and secondly, there has been a general refusal to recognize that psycho-analytic research could not, like a philosophical system, produce a complete and ready-made theoretical structure, but had to find its way step by step along the path towards understanding the intricacies of the mind by making an analytic dissection of both normal and abnormal phenomena. So long as we had to concern ourselves with the study of what is repressed in mental life, there was no need for us to share in any agitated apprehensions as to the whereabouts of the higher side of man. But now that we have embarked upon the analysis of the ego we can give an answer to all those whose moral sense has been shocked and who have complained that there must surely be a higher nature in man: 'Very true,' we can say, 'and here we have that higher nature, in this ego ideal or super-ego, the representative of our relation to our parents. When we were little children we knew these higher natures, we admired them and feared them; and later we took them into ourselves.'

The ego ideal is therefore the heir of the Oedipus complex, and thus it is also the expression of the most powerful impulses and most important libidinal vicissitudes of the id. By setting up this ego ideal, the ego has mastered the Oedipus complex and at the same time placed itself in subjection to the id. Whereas the ego is essentially the representative of the external world, of reality, the super-ego stands in contrast to it as the representative of the internal world, of the id. Conflicts between the ego and the ideal will, as we are now prepared to find, ultimately reflect the contrast between what is real and what is psychical, between the external world and the internal world.

Through the forming of the ideal, what biology and the vicissitudes of the human species have created in the id and left behind in it is taken over by the ego and re-experienced in relation to itself as an individual. Owing to the way in which the ego ideal is formed, it has the most abundant links with the phylogenetic acquisition of each individual - his archaic heritage. What has belonged to the lowest part of the mental life of each of us is changed, through the formation of the ideal, into what is highest in the human mind by our scale of values. It would be vain, however, to attempt to localize the ego ideal, even in the sense in which we have localized the ego, or to work it into any of the analogies with the help of which we have tried to picture the relation between the ego and the id.

It is easy to show that the ego ideal answers to everything that is expected of the higher nature of man. As a substitute for a longing for the father, it contains the germ from which all religions have evolved. The self-judgement which declares that the ego falls short of its ideal produces the religious sense of humility to which the believer appeals in his longing. As a child grows up, the role of father is carried on by teachers and others in authority; their injunctions and prohibitions remain powerful in the ego ideal and continue, in the form of conscience, to exercise the moral censorship. The tension between the demands of conscience and the actual performances of the ego is experienced as a sense of guilt. Social feelings rest on identifications with other people, on the basis of having the same ego ideal.

Religion, morality, and a social sense - the chief elements in the higher side of man¹ - were originally one and the same thing. According to the hypothesis which I put forward in *Totem and Taboo* they were acquired phylogenetically out of the father-complex: religion and moral restraint through the process of mastering the Oedipus complex itself, and social feeling through the necessity for overcoming the rivalry that then remained between the members of the younger generation. The male sex seems to have taken the lead in all these moral acquisitions; and they seem to have then been transmitted to women by cross-inheritance. Even to-day the social feelings arise in the individual as a superstructure built upon impulses of jealous rivalry against his brothers and sisters. Since the hostility cannot be satisfied, an identification with the former rival develops. The study of mild cases of homosexuality confirms the suspicion that in this instance, too, the identification is a substitute for an affectionate object-choice which has taken the place of the aggressive, hostile attitude.²

¹ I am at the moment putting science and art on one side.

² Cf. *Group Psychology* (1921*c*) and 'Some Neurotic Mechanisms in Jealousy, Paranoia and Homosexuality' (1922*b*).

With the mention of phylogenesis, however, fresh problems arise, from which one is tempted to draw cautiously back. But there is no help for it, the attempt must be made - in spite of a fear that it will lay bare the inadequacy of our whole effort. The question is: which was it, the ego of primitive man or his id, that acquired religion and morality in those early days out of the father-complex? If it was his ego, why do we not speak simply of these things being inherited by the ego? If it was the id, how does that agree with the character of the id? Or are we wrong in carrying the differentiation between ego, super-ego, and id back into such early times? Or should we not honestly confess that our whole conception of the processes in the ego is of no help in understanding phylogenesis and cannot be applied to it?

Let us answer first what is easiest to answer. The differentiation between ego and id must be attributed not only to primitive man but even to much simpler organisms, for it is the inevitable expression of the influence of the external world. The super-ego, according to our hypothesis, actually originated from the experiences that led to totemism. The question whether it was the ego or the id that experienced and acquired these things soon comes to nothing. Reflection at once shows us that no external vicissitudes can be experienced or undergone by the id, except by way of the ego, which is the representative of the external world to the id. Nevertheless it is not possible to speak of direct inheritance in the ego. It is here that the gulf between an actual individual and the concept of a species becomes evident. Moreover, one must not take the difference between ego and id in too hard-and-fast a sense, nor forget that the ego is a specially differentiated part of the id. The experiences of the ego seem at first to be lost for inheritance; but, when they have been repeated often enough and with sufficient strength in many individuals in successive generations, they transform themselves, so to say, into experiences of the id, the impressions of which are preserved by heredity. Thus in the id, which is capable of being inherited, are harboured residues of the existences of countless egos; and, when the ego forms its super-ego out of the id, it may perhaps only be reviving shapes of former egos and be bringing them to resurrection.

The way in which the super-ego came into being explains how it is that the early conflicts of the ego with the object-cathexes of the id can be continued in conflicts with their heir, the super-ego. If the ego has not succeeded in properly mastering the Oedipus complex, the energetic cathexis of the latter, springing from the id, will come into operation once more in the reaction-formation of the ego ideal. The abundant communication between the ideal and these *Ucs.* instinctual impulses solves the puzzle of how it is that the ideal itself can to a great extent remain unconscious and inaccessible to the ego. The struggle which once raged in the deepest strata of the mind, and was not brought to an end by rapid sublimation and identification, is now continued in a higher region, like the Battle of the Huns in Kaulbach's painting.

IV

THE TWO CLASSES OF INSTINCTS

We have already said that, if the differentiation we have made of the mind into an id, an ego, and a super-ego represents any advance in our knowledge, it ought to enable us to understand more thoroughly the dynamic relations within the mind and to describe them more clearly. We have also already concluded that the ego is especially under the influence of perception, and that, speaking broadly, perceptions may be said to have the same significance for the ego as instincts have for the id. At the same time the ego is subject to the influence of the instincts, too, like the id, of which it is, as we know, only a specially modified part.

I have lately developed a view of the instincts¹ which I shall here hold to and take as the basis of my further discussions. According to this view we have to distinguish two classes of instincts, one of which, the sexual instincts or Eros, is by far the more conspicuous and accessible to study. It comprises not merely the uninhibited sexual instinct proper and the instinctual impulses of an aim-inhibited or sublimated nature derived from it, but also the self-preservative instinct, which must be assigned to the ego and which at the beginning of our analytic work we had good reason for contrasting with the sexual object-instincts. The second class of instincts was not so easy to point to; in the end we came to recognize sadism as its representative. On the basis of theoretical considerations, supported by biology, we put forward the hypothesis of a death instinct, the task of which is to lead organic life back into the inanimate state; on the other hand, we supposed that Eros, by bringing about a more and more far-reaching combination of the particles into which living substance is dispersed, aims at complicating life and at the same time, of course, at preserving it. Acting in this way, both the instincts would be conservative in the strictest sense of the word, since both would be endeavouring to re-establish a state of things that was disturbed by the emergence of life. The emergence of life would thus be the cause of the continuance of life and also at the same time of the striving towards death; and life itself would be a conflict and compromise between these two trends. The problem of the origin of life would remain a cosmological one; and the problem of the goal and purpose of life would be answered dualistically.

¹ *Beyond the Pleasure Principle.*

On this view, a special physiological process (of anabolism of catabolism) would be associated with each of the two classes of instincts; both kinds of instinct would be active in every particle of living substance, though in unequal proportions, so that some one substance might be the principal representative of Eros.

This hypothesis throws no light whatever upon the manner in which the two classes of instincts are fused, blended, and alloyed with each other; but that this takes place regularly and very extensively is an assumption indispensable to our conception. It appears that, as a result of the combination of unicellular organisms into multicellular forms of life, the death instinct of the single cell can successfully be neutralized and the destructive impulses be diverted on to the external world through the instrumentality of a special organ. This special organ would seem to be the muscular apparatus; and the death instinct would thus seem to express itself - though probably only in part - as an instinct of destruction directed against the external world and other organisms.

Once we have admitted the idea of a fusion of the two classes of instincts with each other, the possibility of a - more or less complete - 'defusion' of them forces itself upon us. The sadistic component of the sexual instinct would be a classical example of a serviceable instinctual fusion; and the sadism which has made itself independent as a perversion would be typical of a defusion, though not of one carried to extremes. From this point we obtain a view of a great domain of facts which has not before been considered in this light. We perceive that for purposes of discharge the instinct of destruction is habitually brought into the service of Eros; we suspect that the epileptic fit is a product and indication of an instinctual defusion; and we come to understand that instinctual defusion and the marked emergence of the death instinct call for particular consideration among the effects of some severe neuroses - for instance, the obsessional neuroses. Making a swift generalization, we might conjecture that the essence of a regression of libido (e. g. from the genital to the sadistic-anal phase) lies in a defusion of instincts, just as, conversely, the advance from the earlier phase to the definitive genital one would be conditioned by an accession of erotic components. The question also arises whether ordinary ambivalence, which is so often unusually strong in the constitutional disposition to neurosis, should not be regarded as the product of a defusion; ambivalence, however, is such a fundamental phenomenon that it more probably represents an instinctual fusion that has not been completed.

It is natural that we should turn with interest to enquire whether there may not be instructive connections to be traced between the structures we have assumed to exist - the ego, the super-ego and the id - on the one hand and the two classes of instincts on the other; and, further, whether the pleasure principle which dominates mental processes can be shown to have any constant relation both to the two classes of instincts and to these differentiations which we have drawn in the mind. But before we discuss this, we must clear away a doubt which arises concerning the terms in which the problem itself is stated. There is, it is true, no doubt about the pleasure principle, and the differentiation within the ego has good clinical justification; but the distinction between the two classes of instincts does not seem sufficiently assured and it is possible that facts of clinical analysis may be found which will do away with its pretension.

One such fact there appears to be. For the opposition between the two classes of instincts we may put the polarity of love and hate. There is no difficulty in finding a representative of Eros; but we must be grateful that we can find a representative of the elusive death instinct in the instinct of destruction, to which hate points the way. Now, clinical observation shows not only that love is with unexpected regularity accompanied by hate (ambivalence), and not only that in human relationships hate is frequently a forerunner of love, but also that in a number of circumstances hate changes into love and love into hate. If this change is more than a mere succession in time - if, that is, one of them actually turns into the other - then clearly the ground is cut away from under a distinction so fundamental as that between erotic instincts and death instincts, one which presupposes physiological processes running in opposite directions.

Now the case in which someone first loves and then hates the same person (or the reverse) because that person has given him cause for doing so, has obviously nothing to do with our problem. Nor has the other case, in which feelings of love that have not yet become manifest express themselves to begin with by hostility and aggressive tendencies; for it may be that here the destructive component in the object-cathexis has hurried on ahead and is only later on joined by the erotic one. But we know of several instances in the psychology of the neuroses in which it is more plausible to suppose that a transformation does take place. In persecutory paranoia the patient fends off an excessively strong homosexual attachment to some particular person in a special way; and as a result this person whom he loved most becomes a persecutor, against whom the patient directs an often dangerous aggressiveness. Here we have a right to interpolate a previous phase which has transformed the love into hate. In the case of the origin of homosexuality, and of desexualized social feelings as well, analytic investigation has only recently taught us to recognize that violent feelings of rivalry are present which lead to aggressive inclinations, and that it is only after these have been surmounted that the formerly hated object becomes the loved one or gives rise to an identification. The question arises whether in these instances we are to assume a direct transformation of hate into love. It is clear that here the changes are purely internal and an alteration in the behaviour of the object plays no part in them.

There is another possible mechanism, however, which we have come to know of by analytic investigation of the processes concerned in the change in paranoia. An ambivalent attitude is present from the outset and the transformation is effected by means of a reactive displacement of cathexis, energy being withdrawn from the erotic impulse and added to the hostile one.

Not quite the same thing but something like it happens when the hostile rivalry leading to homosexuality is overcome. The hostile attitude has no prospect of satisfaction; consequently - for economic reasons, that is - it is replaced by a loving attitude for which there is more prospect of satisfaction - that is, possibility of discharge. So we see that we are not obliged in any of these cases to assume a direct transformation of hate into love, which would be incompatible with the qualitative distinction between the two classes of instincts.

It will be noticed, however, that by introducing this other mechanism of changing love into hate, we have tacitly made another assumption which deserves to be stated explicitly. We have reckoned as though there existed in the mind - whether in the ego or in the id - a displaceable energy, which, neutral in itself, can be added to a qualitatively differentiated erotic or destructive impulse, and augment its total cathexis. Without assuming the existence of a displaceable energy of this kind we can make no headway. The only question is where it comes from, what it belongs to, and what it signifies.

The problem of the quality of instinctual impulses and of its persistence throughout their various vicissitudes is still very obscure and has hardly been attacked up to the present. In the sexual component instincts, which are especially accessible to observation, it is possible to perceive a few processes which are in the same category as what we are discussing. We see, for instance, that some degree of communication exists between the component instincts, that an instinct deriving from one particular erotogenic source can make over its intensity to reinforce another component instinct originating from another source, that the satisfaction of one instinct can take the place of the satisfaction of another, and more facts of the same nature - which must encourage us to venture upon certain hypotheses.

In the present discussion, moreover, I am only putting forward a hypothesis; I have no proof to offer. It seems a plausible view that this displaceable and neutral energy, which is no doubt active in both in the ego and in the id, proceeds from the narcissistic store of libido - that it is desexualized Eros. (The erotic instincts appear to be altogether more plastic, more readily diverted and displaced than the destructive instincts.) From this we can easily go on to assume that this displaceable libido is employed in the service of the pleasure principle to obviate blockages and to facilitate discharge. In this connection it is easy to observe a certain indifference as to the path along which the discharge takes place, so long as it takes place somehow. We know this trait; it is characteristic of the cathectic processes in the id. It is found in erotic cathexes, where a peculiar indifference in regard to the object displays itself; and it is especially evident in the transferences arising in analysis, which develop inevitably, irrespective of the persons who are their object. Not long ago Rank published some good examples of the way in which neurotic acts of revenge can be directed against the wrong people. Such behaviour on the part of the unconscious reminds one of the comic story of the three village tailors, one of whom had to be hanged because the only village blacksmith had committed a capital offence. Punishment must be exacted even if it does not fall upon the guilty. It was in studying the dream-work that we first came upon this kind of looseness in the displacements brought about by the primary process. In that case it was the objects that were thus relegated to a position of no more than secondary importance, just as in the case we are now discussing it is the paths of discharge. It would be characteristic of the ego to be more particular about the choice both of an object and of a path of discharge.

If this displaceable energy is desexualized libido, it may also be described as *sublimated* energy; for it would still retain the main purpose of Eros - that of uniting and binding - in so far as it helps towards establishing the unity, or tendency to unity, which is particularly characteristic of the ego. If thought processes in the wider sense are to be included among these displacements, then the activity of thinking is also supplied from the sublimation of erotic motive forces.

Here we arrive again at the possibility which has already been discussed that sublimation may take place regularly, through the mediation of the ego. The other case will be recollected, in which the ego deals with the first object-cathexes of the id (and certainly with later ones too) by taking over the libido from them into itself and binding it to the alteration of the ego produced by means of identification. The transformation into ego-libido of course involves an abandonment of sexual aims, a desexualization. In any case this throws light upon an important function of the ego in its relation to Eros. By thus getting hold of the libido from the object-cathexes, setting itself up as sole love-object, and desexualizing or sublimating the libido of the id, the ego is working in opposition to the purposes of Eros and placing itself at the service of the opposing instinctual impulses. It has to acquiesce in some of the other object-cathexes of the id; it has, so to speak, to participate in them. We shall come back later to another possible consequence of this activity of the ego.

This would seem to imply an important amplification of the theory of narcissism. At the very beginning, all the libido is accumulated in the id, while the ego is still in process of formation or is still feeble. The id sends part of this libido out into erotic object-cathexes, whereupon the ego, now grown stronger, tries to get hold of this object-libido and to force itself on the id as a love-object. The narcissism of the ego is thus a secondary one, which has been withdrawn from objects.

Over and over again we find, when we are able to trace instinctual impulses back, that they reveal themselves as derivatives of Eros. If it were not for the considerations put forward in *Beyond the Pleasure Principle*, and ultimately for the sadistic constituents which have attached themselves to Eros, we should have difficulty in holding to our fundamental dualistic point of view. But since we cannot escape that view, we are driven to conclude that the death instincts are by their nature mute and that the clamour of life proceeds for the most part from Eros.¹

¹ In fact, on our view it is through the agency of Eros that the destructive instincts that are directed towards the external world have been diverted from the self.

And from the struggle against Eros! It can hardly be doubted that the pleasure principle serves the id as a compass in its struggle against the libido - the force that introduces disturbances into the process of life. If it is true that Fechner's principle of constancy governs life, which thus consists of a continuous descent towards death, it is the claims of Eros, of the sexual instincts, which, in the form of instinctual needs, hold up the falling level and introduce fresh tensions. The id, guided by the pleasure principle - that is, by the perception of unpleasure - fends off these tensions in various ways. It does so in the first place by complying as swiftly as possible with the demands of the non-desexualized libido - by striving for the satisfaction of the directly sexual trends. But it does so in a far more comprehensive fashion in relation to one particular form of satisfaction in which all component demands converge - by discharge of the sexual substances, which are saturated vehicles, so to speak, of the erotic tensions. The ejection of the sexual substances in the sexual act corresponds in a sense to the separation of soma and germ-plasm. This accounts for the likeness of the condition that follows complete sexual satisfaction to dying, and for the fact that death coincides with the act of copulation in some of the lower animals. These creatures die in the act of reproduction because, after Eros has been eliminated through the process of satisfaction, the death instinct has a free hand for accomplishing its purposes. Finally, as we have seen, the ego, by sublimating some of the libido for itself and its purposes, assists the id in its work of mastering the tensions.

V

THE DEPENDENT RELATIONSHIPS OF THE EGO

The complexity of our subject-matter must be an excuse for the fact that none of the chapter-headings of this book quite correspond to their contents, and that in turning to new aspects of the topic we are constantly harking back to matters that have already been dealt with.

Thus we have said repeatedly that the ego is formed to a great extent out of identifications which take the place of abandoned cathexes by the id; that the first of these identifications always behave as a special agency in the ego and stand apart from the ego in the form of a super-ego, while later on, as it grows stronger, the ego may become more resistant to the influences of such identifications. The super-ego owes its special position in the ego, or in relation to the ego, to a factor which must be considered from two sides: on the one hand it was the first identification and one which took place while the ego was still feeble, and on the other hand it is the heir to the Oedipus complex and has thus introduced the most momentous objects into the ego. The super-ego's relation to the later alterations of the ego is roughly similar to that of the primary sexual phase of childhood to later sexual life after puberty. Although it is accessible to all later influences, it nevertheless preserves throughout life the character given to it by its derivation from the father-complex - namely, the capacity to stand apart from the ego and to master it. It is a memorial of the former weakness and dependence of the ego, and the mature ego remains subject to its domination. As the child was once under a compulsion to obey its parents, so the ego submits to the categorical imperative of its super-ego.

But the derivation of the super-ego from the first object-cathexes of the id, from the Oedipus complex, signifies even more for it. This derivation, as we have already shown, brings it into relation with the phylogenetic acquisitions of the id and makes it a reincarnation of former ego-structures which have left their precipitates behind in the id. Thus the super-ego is always close to the id and can act as its representative *vis-à-vis* the ego. It reaches deep down into the id and for that reason is farther from consciousness than the ego is.¹

¹ It may be said that the psycho-analytic or metapsychological ego stands on its head no less than the anatomical ego - the 'cortical homunculus'.

We shall best appreciate these relations by turning to certain clinical facts, which have long since lost their novelty but which still await theoretical discussion.

There are certain people who behave in a quite peculiar fashion during the work of analysis. When one speaks hopefully to them or expresses satisfaction with the progress of the treatment, they show signs of discontent and their condition invariably becomes worse. One begins by regarding this as defiance and as an attempt to prove their superiority to the physician, but later one comes to take a deeper and juster view. One becomes convinced, not only that such people cannot endure any praise or appreciation, but that they react inversely to the progress of the treatment. Every partial solution that ought to result, and in other people does result, in an improvement or a temporary suspension of symptoms produces in them for the time being an exacerbation of their illness; they get worse during the treatment instead of getting better. They exhibit what is known as a 'negative therapeutic reaction'.

There is no doubt that there is something in these people that sets itself against their recovery, and its approach is dreaded as though it were a danger. We are accustomed to say that the need for illness has got the upper hand in them over the desire for recovery. If we analyse this resistance in the usual way then, even after allowance has been made for an attitude of defiance towards the physician and for fixation to the various forms of gain from illness, the greater part of it is still left over; and this reveals itself as the most powerful of all obstacles to recovery, more powerful than the familiar ones of narcissistic inaccessibility, a negative attitude towards the physician and clinging to the gain from illness.

In the end we come to see that we are dealing with what may be called a 'moral' factor, a sense of guilt, which is finding its satisfaction in the illness and refuses to give up the punishment of suffering. We shall be right in regarding this disheartening explanation as final. But as far as the patient is concerned this sense of guilt is dumb; it does not tell him he is guilty; he does not feel guilty, he feels ill. This sense of guilt expresses itself only as a resistance to recovery which it is extremely difficult to overcome. It is also particularly difficult to convince the patient that this motive lies behind his continuing to be ill; he holds fast to the more obvious explanation that treatment by analysis is not the right remedy for his case.¹

The description we have given applies to the most extreme instances of this state of affairs, but in a lesser measure this factor has to be reckoned with in very many cases, perhaps in all comparatively severe cases of neurosis. In fact it may be precisely this element in the situation, the attitude of the ego ideal, that determines the severity of a neurotic illness. We shall not hesitate, therefore, to discuss rather more fully the way in which the sense of guilt expresses itself under different conditions.

¹ The battle with the obstacle of an unconscious sense of guilt is not made easy for the analyst. Nothing can be done against it directly, and nothing indirectly but the slow procedure of unmasking its unconscious repressed roots, and of thus gradually changing it into a *conscious* sense of guilt. One has a special opportunity for influencing it when this *Ucs.* sense of guilt is a 'borrowed' one - when it is the product of an identification with some other person who was once the object of an erotic cathexis. A sense of guilt that has been adopted in this way is often the sole remaining trace of the abandoned love-relation and not at all easy to recognize as such. (The likeness between this process and what happens in melancholia is unmistakable.) If one can unmask this former object-cathexis behind the *Ucs.* sense of guilt, the therapeutic success is often brilliant, but otherwise the outcome of one's efforts is by no means certain. It depends principally on the intensity of the sense of guilt; there is often no counteracting force of a similar order of strength which the treatment can oppose to it. Perhaps it may depend, too, on whether the personality of the analyst allows of the patient's putting him in the place of his ego ideal, and this involves a temptation for the analyst to play the part of prophet, saviour and redeemer to the patient. Since the rules of analysis are diametrically opposed to the physician's making use of his personality in any such manner, it must be honestly confessed that here we have another limitation to the effectiveness of analysis; after all, analysis does not set out to make pathological reactions impossible, but to give the patient's ego *freedom* to decide one way or the other.

An interpretation of the normal, conscious sense of guilt (conscience) presents no difficulties; it is based on the tension between the ego and the ego ideal and is the expression of a condemnation of the ego by its critical agency. The feelings of inferiority so well known in neurotics are presumably not far removed from it. In two very familiar maladies the sense of guilt is over-strongly conscious; in them the ego ideal displays particular severity and often rages against the ego in a cruel fashion. The attitude of the ego ideal in these two conditions, obsessional neurosis and melancholia, presents, alongside of this similarity, differences that are no less significant.

In certain forms of obsessional neurosis the sense of guilt is over-noisy but cannot justify itself to the ego. Consequently the patient's ego rebels against the imputation of guilt and seeks the physician's support in repudiating it. It would be folly to acquiesce in this, for to do so would have no effect. Analysis eventually shows that the super-ego is being influenced by processes that have remained unknown to the ego. It is possible to discover the repressed impulses which are really at the bottom of the sense of guilt. Thus in this case the super-ego knew more than the ego about the unconscious id.

In melancholia the impression that the super-ego has obtained a hold upon consciousness is even stronger. But here the ego ventures no objection; it admits its guilt and submits to the punishment. We understand the difference. In obsessional neurosis what were in question were objectionable impulses which remained outside the ego, while in melancholic the object to which the super-ego's wrath applies has been taken into the ego through identification.

It is certainly not clear why the sense of guilt reaches such an extraordinary strength in these two neurotic disorders; but the main problem presented in this state of affairs lies in another direction. We shall postpone discussion of it until we have dealt with the other cases in which the sense of guilt remains unconscious.

It is essentially in hysteria and in states of a hysterical type that this is found. Here the mechanism by which the sense of guilt remains unconscious is easy to discover. The hysterical ego fends off a distressing perception with which the criticisms of its super-ego threaten it, in the same way in which it is in the habit of fending off an unendurable object-cathexis - by an act of repression. It is the ego, therefore, that is responsible for the sense of guilt remaining unconscious. We know that as a rule the ego carries out repressions in the service and at the behest of its super-ego; but this is a case in which it has turned the same weapon against its harsh taskmaster. In obsessional neurosis, as we know, the phenomena of reaction-formation predominate; but here the ego succeeds only in keeping at a distance the material to which the sense of guilt refers.

One may go further and venture the hypothesis that a great part of the sense of guilt must normally remain unconscious, because the origin of conscience is intimately connected with the Oedipus complex, which belongs to the unconscious. If anyone were inclined to put forward the paradoxical proposition that the normal man is not only far more immoral than he believes but also far more moral than he knows, psycho-analysis, on whose findings the first half of the assertion rests, would have no objection to raise against the second half.¹

It was a surprise to find that an increase in this *Ucs.* sense of guilt can turn people into criminals. But it is undoubtedly a fact. In many criminals, especially youthful ones, it is possible to detect a very powerful sense of guilt which existed before the crime, and is therefore not its result but its motive. It is as if it was a relief to be able to fasten this unconscious sense of guilt on to something real and immediate.

In all these situations the super-ego displays its independence of the conscious ego and its intimate relations with the unconscious id. Having regard, now, to the importance we have ascribed to preconscious verbal residues in the ego, the question arises whether it can be the case that the super-ego, in so far as it is *Ucs.*, consists in such word-presentations and, if it does not, what else it consists in. Our tentative answer will be that it is as impossible for the super-ego as for the ego to disclaim its origin from things heard; for it is a part of the ego and remains accessible to consciousness by way of these word-presentations (concepts, abstractions). But the *cathectic energy* does not reach these contents of the super-ego from auditory perception (instruction or reading) but from sources in the id.

¹ This proposition is only apparently a paradox; it simply states that human nature has a far greater extent, both for good and for evil, than it thinks it has - i. e. than its ego is aware of through conscious perception.

The question which we put off answering runs as follows: How is it that the super-ego manifests itself essentially as a sense of guilt (or rather, as criticism - for the sense of guilt is the perception in the ego answering to this criticism) and moreover develops such extraordinary harshness and severity towards the ego? If we turn to melancholia first, we find that the excessively strong super-ego which has obtained a hold upon consciousness rages against the ego with merciless violence, as if it had taken possession of the whole of the sadism available in the person concerned. Following our view of sadism, we should say that the destructive component had entrenched itself in the super-ego and turned against the ego. What is now holding sway in the super-ego is, as it were, a pure culture of the death instinct, and in fact it often enough succeeds in driving the ego into death, if the latter does not fend off its tyrant in time by the change round into mania.

The reproaches of conscience in certain forms of obsessional neurosis are as distressing and tormenting, but here the situation is less perspicuous. It is noteworthy that the obsessional neurotic, in contrast to the melancholic, never in fact takes the step of self-destruction; it is as though he were immune against the danger of suicide, and he is far better protected from it than the hysteric. We can see that what guarantees the safety of the ego is the fact that the object has been retained. In obsessional neurosis it has become possible, through a regression to the pregenital organization, for the love-impulses to transform themselves into impulses of aggression against the object. Here again the instinct of destruction has been set free and it seeks to destroy the object, or at least it appears to have that intention. These purposes have not been adopted by the ego and it struggles against them with reaction-formations and precautionary measures; they remain in the id. The super-ego, however, behaves as if the ego were responsible for them and shows at the same time by the seriousness with which it chastises these destructive intentions that they are no mere semblance evoked by regression but an actual substitution of hate for love. Helpless in both directions, the ego defends itself vainly, alike against the instigations of the murderous id and against the reproaches of the punishing conscience. It succeeds in holding in check at least the most brutal actions of both sides; the first outcome is interminable self-torment, and eventually there follows a systematic torturing of the object, in so far as it is within reach.

The dangerous death instincts are dealt with in the individual in various ways: in part they are rendered harmless by being fused with erotic components, in part they are diverted towards the external world in the form of aggression, while to a large extent they undoubtedly continue their internal work unhindered. How is it then that in melancholia the super-ego can become a kind of gathering-place for the death instincts?

From the point of view of instinctual control, of morality, it may be said of the id that it is totally non-moral, of the ego that it strives to be moral, and of the super-ego that it can be super-moral and then become as cruel as only the id can be. It is remarkable that the more a man checks his aggressiveness towards the exterior the more severe - that is aggressive - he becomes in his ego ideal. The ordinary view sees the situation the other way round: the standard set up by the ego ideal seems to be the motive for the suppression of aggressiveness. The fact remains, however, as we have stated it: the more a man controls his aggressiveness, the more intense becomes his ideal's inclination to aggressiveness against his ego. It is like a displacement, a turning round upon his own ego. But even ordinary normal morality has a harshly restraining, cruelly prohibiting quality. It is from this, indeed, that the conception arises of a higher being who deals out punishment inexorably.

I cannot go further in my consideration of these questions without introducing a fresh hypothesis. The super-ego arises, as we know, from an identification with the father taken as a model. Every such identification is in the nature of a desexualization or even of a sublimation. It now seems as though when a transformation of this kind takes place, an instinctual defusion occurs at the same time. After sublimation the erotic component no longer has the power to bind the whole of the destructiveness that was combined with it, and this is released in the form of an inclination to aggression and destruction. This defusion would be the source of the general character of harshness and cruelty exhibited by the ideal - its dictatorial 'Thou shalt'.

Let us again consider obsessional neurosis for a moment. The state of affairs is different here. The defusion of love into aggressiveness has not been effected by the work of the ego, but is the result of a regression which has come about in the id. But this process has extended beyond the id to the super-ego, which now increases its severity towards the innocent ego. It would seem, however, that in this case, no less than in that of melancholia, the ego, having gained control over the libido by means of identification, is punished for doing so by the super-ego through the instrumentality of the aggressiveness which was mixed with the libido.

Our ideas about the ego are beginning to clear, and its various relationships are gaining distinctness. We now see the ego in its strength and in its weaknesses. It is entrusted with important functions. By virtue of its relation to the perceptual system it gives mental processes an order in time and submits them to 'reality-testing'. By interposing the processes of thinking, it secures a postponement of motor discharges and controls the access to motility. This last power is, to be sure, a question more of form than of fact; in the matter of action the ego's position is like that of a constitutional monarch, without whose sanction no law can be passed but who hesitates long before imposing his veto on any measure put forward by Parliament. All the experiences of life that originate from without enrich the ego; the id, however, is its second external world, which it strives to bring into subjection to itself. It withdraws libido from the id and transforms the object-cathexes of the id into ego-structures. With the aid of the super-ego, in a manner that is still obscure to us, it draws upon the experiences of past ages stored in the id.

There are two paths by which the contents of the id can penetrate into the ego. The one is direct, the other leads by way of the ego ideal; which of these two paths they take may, for some mental activities, be of decisive importance. The ego develops from perceiving instincts to controlling them, from obeying instincts to inhibiting them. In this achievement a large share is taken by the ego ideal, which indeed is partly a reaction-formation against the instinctual processes of the id. Psycho-analysis is an instrument to enable the ego to achieve a progressive conquest of the id.

From the other point of view, however, we see this same ego as a poor creature owing service to three masters and consequently menaced by three dangers: from the external world, from the libido of the id, and from the severity of the super-ego. Three kinds of anxiety correspond to these three dangers, since anxiety is the expression of a retreat from danger. As a frontier creature, the ego tries to mediate between the world and the id, to make the id pliable to the world and, by means of its muscular activity, to make the world fall in with the wishes of the id. In point of fact it behaves like the physician during an analytic treatment: it offers itself, with the attention it pays to the real world, as a libidinal object to the id, and aims at attaching the id's libido to itself. It is not only a helper to the id; it is also a submissive slave who courts his master's love. Whenever possible, it tries to remain on good terms with the id; it clothes the id's *Ucs.* commands with its *Pcs.* rationalizations; it pretends that the id is showing obedience to the admonitions of reality, even when in fact it is remaining obstinate and unyielding; it disguises the id's conflicts with reality and, if possible, its conflicts with the super-ego too. In its position midway between the id and reality, it only too often yields to the temptation to become sycophantic, opportunist and lying, like a politician who sees the truth but wants to keep his place in popular favour.

Towards the two classes of instincts the ego's attitude is not impartial. Through its work of identification and sublimation it gives the death instincts in the id assistance in gaining control over the libido, but in so doing it runs the risk of becoming the object of the death instincts and of itself perishing. In order to be able to help in this way it has had itself to become filled with libido; it thus itself becomes the representative of Eros and henceforward desires to live and to be loved.

But since the ego's work of sublimation results in a defusion of the instincts and a liberation of the aggressive instincts in the super-ego, its struggle against the libido exposes it to the danger of maltreatment and death. In suffering under the attacks of the super-ego or perhaps even succumbing to them, the ego is meeting with a fate like that of the protista which are destroyed by the products of decomposition that they themselves have created. From the economic point of view the morality that functions in the super-ego seems to be a similar product of decomposition.

Among the dependent relationships in which the ego stands, that to the super-ego is perhaps the most interesting.

The ego is the actual seat of anxiety. Threatened by dangers from three directions, it develops the flight-reflex by withdrawing its own cathexis from the menacing perception or from the similarly regarded process in the id, and emitting it as anxiety. This primitive reaction is later replaced by the carrying-out of protective cathexes (the mechanism of the phobias). What it is that the ego fears from the external and from the libidinal danger cannot be specified; we know that the fear is of being overwhelmed or annihilated, but it cannot be grasped analytically. The ego is simply obeying the warning of the pleasure principle. On the other hand, we can tell what is hidden behind the ego's dread of the super-ego, the fear of conscience. The superior being, which turned into the ego ideal, once threatened castration, and this dread of castration is probably the nucleus round which the subsequent fear of conscience has gathered; it is this dread that persists as the fear of conscience.

The high-sounding phrase, 'every fear is ultimately the fear of death', has hardly any meaning, and at any rate cannot be justified. It seems to me, on the contrary, perfectly correct to distinguish the fear of death from dread of an object (realistic anxiety) and from neurotic libidinal anxiety. It presents a difficult problem to psycho-analysis, for death is an abstract concept with a negative content for which no unconscious correlative can be found. It would seem that the mechanism of the fear of death can only be that the ego relinquishes its narcissistic libidinal cathexis in a very large measure - that is, that it gives up itself, just as it gives up some *external* object in other cases in which it feels anxiety. I believe that the fear of death is something that occurs between the ego and the super-ego.

We know that the fear of death makes its appearance under two conditions (which, moreover, are entirely analogous to situations in which other kinds of anxiety develop), namely, as a reaction to an external danger and as an internal process, as for instance in melancholia. Once again a neurotic manifestation may help us to understand a normal one.

The fear of death in melancholia only admits of one explanation: that the ego gives itself up because it feels itself hated and persecuted by the super-ego, instead of loved. To the ego, therefore, living means the same as being loved - being loved by the super-ego, which here again appears as the representative of the id. The super-ego fulfils the same function of protecting and saving that was fulfilled in earlier days by the father and later by Providence or Destiny. But, when the ego finds itself in an excessive real danger which it believes itself unable to overcome by its own strength, it is bound to draw the same conclusion. It sees itself deserted by all protecting forces and lets itself die. Here, moreover, is once again the same situation as that which underlay the first great anxiety-state of birth and the infantile anxiety of longing - the anxiety due to separation from the protecting mother.

These considerations make it possible to regard the fear of death, like the fear of conscience, as a development of the fear of castration. The great significance which the sense of guilt has in the neuroses makes it conceivable that common neurotic anxiety is reinforced in severe cases by the generating of anxiety between the ego and the super-ego (fear of castration, of conscience, of death).

The id, to which we finally come back, has no means of showing the ego either love or hate. It cannot say what it wants; it has achieved no unified will. Eros and the death instinct struggle within it; we have seen with what weapons the one group of instincts defends itself against the other. It would be possible to picture the id as under the domination of the mute but powerful death instincts, which desire to be at peace and (prompted by the pleasure principle) to put Eros, the mischief maker, to rest; but perhaps that might be to undervalue the part played by Eros.

A SEVENTEENTH-CENTURY DEMONOLOGICAL NEUROSIS
(1923)

THE SECOND APPEARANCE OF THE DEVIL TO
CHRISTOPH HAIZMANN

Intentionally left blank

A SEVENTEENTH-CENTURY DEMONOLOGICAL NEUROSIS

The neuroses of childhood have taught us that a number of things can easily be seen in them with the naked eye which at a later age are only to be discovered after a thorough investigation. We may expect that the same will turn out to be true of neurotic illnesses in earlier centuries, provided that we are prepared to recognize them under names other than those of our present-day neuroses. We need not be surprised to find that, whereas the neuroses of our unpsychological modern days take on a hypochondriacal aspect and appear disguised as organic illnesses, the neuroses of those early times emerge in demonological trappings. Several authors, foremost among them Charcot, have, as we know, identified the manifestations of hysteria in the portrayals of possession and ecstasy that have been preserved for us in the productions of art. If more attention had been paid to the histories of such cases at the time, it would not have been difficult to retrace in them the subject-matter of a neurosis.

The demonological theory of those dark times has won in the end against all the somatic views of the period of 'exact' science. The states of possession correspond to our neuroses, for the explanation of which we once more have recourse to psychical powers. In our eyes, the demons are bad and reprehensible wishes, derivatives of instinctual impulses that have been repudiated and repressed. We merely eliminate the projection of these mental entities into the external world which the middle ages carried out; instead, we regard them as having arisen in the patient's internal life, where they have their abode.

I

THE STORY OF CHRISTOPH HAIZMANN
THE PAINTER

I am indebted to the friendly interest of Hofrat Dr. Payer-Thurn, director of the former Imperial Fideikommissbibliothek of Vienna, for the opportunity of studying a seventeenth century demonological neurosis of this kind. Payer-Thurn had discovered a manuscript in this library which originated from the shrine of Mariazell and in which there was a detailed account of a miraculous redemption from a pact with the Devil through the grace of the Blessed Virgin Mary. His interest was aroused by the resemblance of this story to the legend of Faust, and has led him to undertake the exhaustive publication and editing of the material. Finding, however, that the person whose redemption was described had been subject to convulsive seizures and visions he approached me for a medical opinion on the case. We came to an agreement to publish our investigations independently and separately. I should like to take this opportunity of thanking him for his original suggestion and for the many ways in which he has assisted me in the study of the manuscript.

This demonological case history leads to really valuable findings which can be brought to light without much interpretation - much as a vein of pure metal may sometimes be struck which must elsewhere be laboriously smelted from the ore.

The manuscript, an exact copy of which lies before me, falls into two quite distinct sections. One is a report, written in Latin, by a monastic scribe or compiler; the other is a fragment from the patient's diary, written in German. The first succession contains a preface and a description of the actual miraculous cure. The second can scarcely have been of any significance for the reverend Fathers but so much the more is it of value for us. It serves in large part to confirm our judgement of the case, which might otherwise have been hesitant, and we have good cause to be grateful to the clergy for having preserved the document although it added nothing to support the tenor of their views and, indeed, may rather have weakened it.

But before going further into the composition of this little manuscript brochure, which bears the title *Trophaeum Mariano-Cellense*, I must relate a part of its contents, which I take from the preface.

On September 5, 1677, the painter Christoph Haizmann, a Bavarian, was brought to Mariazell, with a letter of introduction from the village priest of Pottenbrunn (in lower Austria) not far away.¹ The letter states that the man had been staying in Pottenbrunn for some months, pursuing his occupation of painting. On August 29, while in the church there, he had been seized with frightful convulsions. As these convulsions recurred during the following days, he had been examined by the *Praefectus Dominii Pottenbrunnensis* with a view to discovering what it was that was oppressing him and whether perhaps he had entered into illicit traffic with the Evil Spirit.² Upon this, the man had admitted that nine years before, when he was in a state of despondency about his art and doubtful whether he could support himself, he had yielded to the Devil, who had tempted him nine times, and that he had given him his bond in writing to belong to him in body and soul after a period of nine years. This period would expire on the twenty-fourth day of the current month.³ The letter went on to say that the unfortunate man had repented and was convinced that only the grace of the Mother of God at Mariazell could save him, by compelling the Evil One to deliver up the bond, which had been written in blood. For this reason the village priest ventured to recommend *miserum hunc hominem omni auxilio destitutum* to the benevolence of the Fathers of Mariazell.

So far the narrative of Leopoldus Braun, the village priest of Pottenbrunn, dated September 1, 1677.

¹ No mention is anywhere made of the painter's age. The context suggests that he was a man of between thirty and forty, probably nearer the lower figure. He died, as we shall see, in 1700.

² We will merely note in passing the possibility that this interrogation inspired in the sufferer - 'suggested' to him - the phantasy of his pact with the Devil.

³ *Quorum et finis 24 mensis hujus futurus appropinquat.*

We can now proceed with the analysis of the manuscript. It consists of three parts:

(1) A coloured title-page representing the scene of the signing of the pact and the scene of the redemption in the chapel of Mariazell. On the next sheet are eight pictures, also coloured, representing the subsequent appearances of the Devil, with a short legend in German attached to each. These pictures are not the originals; they are copies - faithful copies, we are solemnly assured - of the original paintings by Christoph Haizmann.

(2) The actual *Trophaeum Mariano-Cellense* (in Latin), the work of a clerical compiler who signs himself at the foot 'P.A.E.' and appends to these initials four lines of verse containing his biography. The *Trophaeum* ends with a deposition by the Abbot Kilian of St. Lambert, dated September 12, 1729, which is in a different handwriting from that of the compiler. It testifies to the exact correspondence of the manuscript and the pictures with the originals preserved in the archives. There is no mention of the year in which the *Trophaeum* was compiled. We are free to assume that it was done in the same year in which the Abbot Kilian made his deposition - that is, in 1729; or, since the last date mentioned in the text is 1714 -, we may put the compiler's work somewhere between the years 1714 and 1729. The miracle which was to be preserved from oblivion by this manuscript occurred in 1677 - that is to say, between thirty-seven and fifty-two years earlier.

(3) The painter's diary, written in German and covering the period from his redemption in the chapel till January 13 of the following year, 1678. It is inserted in the text of the *Trophaeum* near the end.

The core of the actual *Trophaeum* consists of two pieces of writing: the letter of introduction, mentioned above, from the village priest, Leopold Braun of Pottenbrunn, dated September 1, 1677, and the report by the Abbot Franciscus of Mariazell and St. Lambert, describing the miraculous cure. This is dated September 12, 1677, that is to say, only a few days later. The activity of the editor or compiler, P.A.E., has provided a preface which as it were fuses the contents of these two documents; he has also added some connecting passages of little importance, and, at the end, an account of the subsequent vicissitudes of the painter, based on enquiries made in the year 1714.¹

The painter's previous history is thus told three times over in the *Trophaeum*: (1) in the village priest of Pottenbrunn's letter of introduction, (2) in the formal report by the Abbot Franciscus and (3) in the editor's preface. A comparison of these three sources discloses certain discrepancies which it will be not unimportant for us to follow up.

I can now continue with the painter's story. After he had undergone a prolonged period of penance and prayer at Mariazell, the Devil appeared to him in the sacred Chapel at midnight, on September 8, the Nativity of the Virgin, in the form of a winged dragon, and gave him back the pact, which was written in blood. We shall learn later, to our surprise, that *two* bonds with the Devil appear in Christoph Haizmann's story - an earlier one, written in black ink, and a later one, written in blood. The one referred to in the description of the scene of exorcism, as can also be seen from the picture on the title-page, is the one written in blood - that is, the later one.

¹ This would seem to suggest that the *Trophaeum*, too, dates from 1714.

At this point a doubt as to the credibility of the clerical reporters may well arise in our minds and warn us not to waste our labours on a product of monastic superstition. We are told that several clerics, mentioned by name, assisted at the exorcism and were present in the Chapel when the Devil appeared. If it had been asserted that they, too, saw the Devil appear in the form of a dragon and offer the painter the paper written in red (*Schedam sibi porrigentem conspexisset*), we should be faced by several unpleasant possibilities, among which that of a collective hallucination would be the mildest. But the Abbot Franciscus's testimony dispels this doubt. Far from asserting that the assisting clerics saw the Devil too, he only states in straightforward and sober words that the painter suddenly tore himself away from the Fathers who were holding him, rushed into the corner of the Chapel where he saw the apparition, and then returned with the paper in his hand.¹

The miracle was great, and the victory of the Holy Mother over Satan without question; but unfortunately the cure was not a lasting one. It is once more to the credit of the clergy that they have not concealed this. After a short time the painter left Mariazell in the best of health and went to Vienna, where he lived with a married sister. On October 11 fresh attacks began, some of them very severe, and these are reported in the diary until January 13. They consisted in visions and '*absences*', in which he saw and experienced every kind of thing, in convulsive seizures accompanied by the most painful sensations, on one occasion in paralysis of the legs, and so on. This time, however, it was not the Devil who tormented him; it was by sacred figures that he was vexed - by Christ and by the Blessed Virgin herself. It is remarkable that he suffered no less through these heavenly manifestations and the punishments they inflicted on him than he had formerly through his traffic with the Devil. In his diary, indeed, he included these fresh experiences too as manifestations of the Devil; and when, in May, 1678, he returned to Mariazell, he complained of *maligini Spiritus manifestationes*.

¹ . . . *ipsumque Daemonem ad Aram Sac. Cellae per fenestrellam in cornu Epistolae, Schedam sibi porrigentem conspexisset, eo advolans e Religiosorum manibus, qui eum tenebant, ipsam Schedam ad manum obtinuit. . . .*

He told the reverend Fathers that his reason for returning was that he had to require the Devil to give him back another, earlier bond, which had been written in ink.¹ This time once more the Blessed Virgin and the pious Fathers helped him to obtain the fulfilment of his request. As to how this came about, however, the report is silent. It merely states shortly: *quâ iuxta votum redditâ* - he prayed once again and received the pact back. After this he felt quite free and entered the Order of the Brothers Hospitallers.

We have occasion yet again to acknowledge that in spite of the obvious purpose of his efforts, the compiler has not been tempted into departing from the veracity required of a case history. For he does not conceal the outcome of the enquiry that was made in 1714 from the Superior of the Monastery of the Brothers Hospitallers concerning the painter's later history. The Reverend Pater Provincialis reported that Brother Chrysostomus had again been repeatedly tempted by the Evil Spirit, who tried to seduce him into making a fresh pact (though this only happened 'when he had drunk somewhat too much wine'). But by the grace of God, it had always been possible to repel these attempts. Brother Chrysostomus had died of a hectic fever 'peacefully and of good comfort' in the year 1700 in the Monastery of the Order, at Neustatt on the Moldau.

¹ This bond had been signed in September, 1668, and by May, 1678, nine and a half years later, it would long since have fallen due.

II

THE MOTIVE FOR THE PACT WITH THE DEVIL

If we look at this bond with the Devil as if it were the case history of a neurotic, our interest will turn in the first instance to the question of its motivation, which is, of course, intimately connected with its exciting cause. Why does anyone sign a bond with the Devil? Faust, it is true, asked contemptuously: 'Was willst du armer Teufel geben?' But he was wrong. In return for an immortal soul, the Devil has many things to offer which are highly prized by men: wealth, security from danger, power over mankind and the forces of nature, even magical arts, and, above all else, enjoyment - the enjoyment of beautiful women. These services performed or undertakings made by the Devil are usually mentioned specifically in the agreement made with him.¹ What, then, was the motive which induced Christoph Haizmann to make his pact?

Curiously enough, it was none of these very natural wishes. To put the matter beyond doubt, one has only to read the short remarks attached by the painter to his illustrations of the apparitions of the Devil. For example, the caption to the third vision runs: 'On the third occasion within a year and a half, he appeared to me in this loathsome shape, with a book in his hand which was full of magic and black arts . . .' But from the legend attached to a later apparition we learn that the Devil reproached him violently for having 'burnt his beforementioned book', and threatened to tear him to pieces if he did not give it back.

¹ Cf. *Faust*, Part I, Scene 4:

Ich will mich *hier* zu deinem Dienst verbinden,
Auf deinem Wink nicht rasten und nicht ruhn;
Wenn wir uns *drüben* wieder finden,
So sollst du mir das Gleiche thun.

At his fourth appearance the Devil showed him a large yellow money-bag and a great ducat and promised him to give him as many of these as he wanted at any time. But the painter is able to boast that he 'had taken nothing whatever of the kind'.

Another time the Devil asked him to turn to enjoyment and entertainment, and the painter remarks that 'this indeed came to pass at his desire; but I did not continue for more than three days and it was then brought to an end'.

Since he rejected magical arts, money and pleasures when they were offered him by the Devil, and still less made them conditions of the pact, it becomes really imperative to know what the painter in fact wanted from the Devil when he signed a bond with him. *Some* motive he must have had for his dealings with the Devil.

On this point, too, the *Trophaeum* provides us with reliable information. He had become low-spirited, was unable or unwilling to work properly and was worried about making a livelihood; that is to say, he was suffering from melancholic depression, with an inhibition in his work and (justified) fears about his future. We can see that what we are dealing with really is a case history. We learn, too, the exciting cause of the illness, which the painter himself, in the caption to one of his pictures of the Devil, actually calls a melancholia ('that I should seek diversion and banish melancholy'). The first of our three sources of information, the village priest's letter of introduction, speaks, it is true, only of the state of depression ('*dum artis suae progressum emolumentumque secuturum pusillanimitas perpenderet*'), but the second source, the Abbot Franciscus's report, tells us the cause of this despondency or depression as well. He says: '*acceptâ aliquâ pusillanimitate ex morte parentis*'; and in the compiler's preface the same words are used, though in a reversed order: ('*ex morte parentis acceptâ aliquâ pusillanimitate*'). His father, then, had died and he had in consequence fallen into a state of melancholia; whereupon the Devil had approached him and asked him why he was so downcast and sad, and had promised 'to help him in every way and to give him support'.¹

¹ The first picture on the title-page and its caption represent the Devil in the form of an 'honest citizen'.

Here was a person, therefore, who signed a bond with the Devil in order to be freed from a state of depression. Undoubtedly an excellent motive, as anyone will agree who can have an understanding sense of the torments of such a state and who knows as well how little medicine can do to alleviate this ailment. Yet no one who has followed the story so far as this would be able to guess what the wording of this bond (or rather, of these two bonds)¹ with the Devil actually was.

These bonds bring us two great surprises. In the first place, they mention no *undertaking* given by the Devil in return for whose fulfilment the painter pledges his eternal bliss, but only a *demand* made by the Devil which the painter must satisfy. It strikes us as quite illogical and absurd that this man should give up his soul, not for something he is to *get* from the Devil but for something he is to *do* for him. But the undertaking given by the *painter* seems even stranger.

The first 'syngrapha', written in ink, runs as follows: 'Ich Christoph Haizmann undterschreibe mich disen Herrn sein leibeigener Sohn auff 9. Jahr. 1669 Jahr.' The second, written in blood, runs:-

'Anno 1669.

'Christoph Haizmann. Ich verschreibe mich disen Satan ich sein leibeigner Sohn zu sein, und in 9. Jahr ihm mein Leib und Seel zuzugeheren.'

¹ Since there were two of them - the first written in ink, and the second written about a year later in blood - both said still to be in the treasury of Mariazell and to be transcribed in the *Trophaeum*.

All our astonishment vanishes, however, if we read the text of the bonds in the sense that what is represented in them as a demand made by the Devil is, on the contrary, a service performed by him - that is to say, it is a demand made by the *painter*. The incomprehensible pact would in that case have a straightforward meaning and could be paraphrased thus. The Devil undertakes to replace the painter's lost father for nine years. At the end of that time the painter becomes the property, body and soul, of the Devil, as was the usual custom in such bargains. The train of thought which motivated the painter in making the pact seems to have been this: his father's death had made him lose his spirits and his capacity to work; if he could only obtain a father-substitute he might hope to regain what he had lost.

A man who has fallen into a melancholia on account of his father's death must really have been fond of him. But, if so, it is very strange that such a man should have hit upon the idea of taking the Devil as a substitute for the father whom he loved.

III

THE DEVIL AS A FATHER-SUBSTITUTE

I fear that sober critics will not be prepared to admit that this fresh interpretation has made the meaning of this pact with the Devil clear. They will have two objections to make to it.

In the first place they will say that it is not necessary to regard the bond as a contract in which the undertakings of both parties have been set out. On the contrary, they will argue, it contains only the painter's undertaking; the Devil's is omitted from the text, and is, as it were, *sousentendu*: the painter gives *two* undertakings - firstly to be the Devil's son for nine years, and secondly to belong to him entirely after death. In this way one of the premisses on which our conclusion is built would be disposed of.

The second objection will be that we are not justified in attaching any special importance to the expression 'the Devil's bounden son'; that this is no more than a common figure of speech, which anyone could interpret in the same way as the reverend Fathers may have done. For in their Latin translation they did not mention the relationship of son promised in the bonds, but merely say that the painter '*mancipavit* himself - made himself a bondslave - to the Evil One and had undertaken to lead a sinful life and to deny God and the Holy Trinity. Why depart from this obvious and natural view of the matter?'¹ The position would simply be that a man, in the torment and perplexity of a melancholic depression, signs a bond with the Devil, to whom he ascribes the greatest therapeutic power. That the depression was occasioned by his father's death would then be irrelevant; the occasion might quite as well have been something else.

¹ In point of fact, when we come to consider later at what time and for whom these bonds were drawn up, we shall realize that their text had to be expressed in unobtrusive and generally comprehensible terms. It is enough for us, however, that it contains an ambiguity which we can take as the starting-point of our discussion.

All this sounds convincing and reasonable. Psycho-analysis has once more to meet the reproach that it makes hair-splitting complications in the simplest things and sees mysteries and problems where none exist, and that it does this by laying undue stress on insignificant and irrelevant details, such as occur every where, and making them the basis of the most far-reaching and strangest conclusions. It would be useless for us to point out that this rejection of our interpretation would do away with many striking analogies and break a number of subtle connections which we are able to demonstrate in this case. Our opponents will say that those analogies and connections do not in fact exist, but have been imported into the case by us with quite uncalled-for ingenuity.

I will not preface my reply with the words, 'to be honest' or 'to be candid', for one must always be able to be these things without any special preliminaries. I will instead say quite simply that I know very well that no reader who does not already believe in the justifiability of the psycho-analytic mode of thought will acquire that belief from the case of the seventeenth-century painter, Christoph Haizmann. Nor is it my intention to make use of this case as evidence of the validity of psycho-analysis. On the contrary, I presuppose its validity and am employing it to throw light on the painter's demonological illness. My justification for doing so lies in the success of our investigations into the nature of the neuroses in general. We may say in all modesty that to-day even the more obtuse among our colleagues and contemporaries are beginning to realize that no understanding of neurotic states can be reached without the help of psycho-analysis.

'These shafts can conquer Troy, these shafts alone'

as Odysseus confesses in the *Philoctetes* of Sophocles.

If we are right in regarding our painter's bond with the Devil as a neurotic phantasy, there is no need for any further apology for considering it psycho-analytically. Even small indications have a meaning and importance, and quite specially when they are related to the conditions under which a neurosis originates. To be sure, it is as possible to overvalue as to undervalue them, and it is a matter of judgement how far one should go in exploiting them. But anyone who does not believe in psycho-analysis - or, for the matter of that, even in the Devil - must be left to make what he can of the painter's case, whether he is able to furnish an explanation of his own or whether he sees nothing in it that needs explaining.

We therefore come back to our hypothesis that the Devil with whom the painter signed the bond was a direct substitute for his father. And this is borne out by the shape in which the Devil first appeared to him - as an honest elderly citizen with a brown beard, dressed in a red cloak and leaning with his right hand on a stick, with a black dog beside him¹ (cf. the first picture). Later on his appearance grows more and more terrifying - more mythological, one might say. He is equipped with horns, eagle's claws and bat's wings. Finally he appears in the chapel as a flying dragon. We shall have to come back later to a particular detail of his bodily shape.

It does indeed sound strange that the Devil should be chosen as a substitute for a loved father. But this is only so at first sight, for we know a good many things which lessen our surprise. To begin with, we know that God is a father-substitute; or, more correctly, that he is an exalted father; or, yet again, that he is a copy of a father as he is seen and experienced in childhood - by individuals in their own childhood and by mankind in its prehistory as the father of the primitive and primal horde. Later on in life the individual sees his father as something different and lesser. But the ideational image belonging to his childhood is preserved and becomes merged with the inherited memory-traces of the primal father to form the individual's idea of God. We also know, from the secret life of the individual which analysis uncovers, that his relation to his father was perhaps ambivalent from the outset, or, at any rate, soon became so. That is to say, it contained two sets of emotional impulses that were opposed to each other: it contained not only impulses of an affectionate and submissive nature, but also hostile and defiant ones. It is our view that the same ambivalence governs the relations of mankind to its Deity. The unresolved conflict between, on the one hand, a longing for the father and, on the other, a fear of him and a son's defiance of him, has furnished us with an explanation of important characteristics of religion and decisive vicissitudes in it.²

¹ In Goethe, a black dog like this turns into the Devil himself.

² Cf. *Totem and Taboo* (1912-13) and Reik (1919).

Concerning the Evil Demon, we know that he is regarded as the antithesis of God and yet is very close to him in his nature. His history has not been so well studied as that of God; not all religions have adopted the Evil Spirit, the opponent of God, and his prototype in the life of the individual has so far remained obscure. One thing, however, is certain: gods can turn into evil demons when new gods oust them. When one people has been conquered by another, their fallen gods not seldom turn into demons in the eyes of the conquerors. The evil demon of the Christian faith - the Devil of the Middle Ages - was, according to Christian mythology, himself a fallen angel and of a godlike nature. It does not need much analytic perspicacity to guess that God and the Devil were originally identical - were a single figure which was later split into two figures with opposite attributes.¹ In the earliest ages of religion God himself still possessed all the terrifying features which were afterwards combined to form a counterpart of him.

We have here an example of the process, with which we are familiar, by which an idea that has a contradictory - an ambivalent - content becomes divided into two sharply contrasted opposites. The contradictions in the original nature of God are, however, a reflection of the ambivalence which governs the relation of the individual to his personal father. If the benevolent and righteous God is a substitute for his father, it is not to be wondered at that his hostile attitude to his father, too, which is one of hating and fearing him and of making complaints against him, should have come to expression in the creation of Satan. Thus the father, it seems, is the individual prototype of both God and the Devil. But we should expect religions to bear ineffaceable marks of the fact that the primitive primal father was a being of unlimited evil - a being less like God than the Devil.

¹ Cf. Reik, 1923, Chapter VII.

It is true that it is by no means easy to demonstrate the traces of this satanic view of the father in the mental life of the individual. When a boy draws grotesque faces and caricatures, we may no doubt be able to show that he is jeering at his father in them; and when a person of either sex is afraid of robbers and burglars at night, it is not hard to recognize these as split off portions of the father.¹ The animals, too, which appear in children's animal phobias are most often father-substitutes, as were the totem animals of primaeval times. But that the Devil is a duplicate of the father and can act as a substitute for him has not been shown so clearly elsewhere as in the demonological neurosis of this seventeenth-century painter. That is why, at the beginning of this paper, I foretold that a demonological case history of this kind would yield in the form of pure metal material which, in the neuroses of a later epoch (no longer superstitious but hypochondriacal instead) has to be laboriously extracted by analytic work from the ore of free associations and symptoms.² A deeper penetration into the analysis of our painter's illness will probably bring stronger conviction. It is no unusual thing for a man to acquire a melancholic depression and an inhibition in his work as a result of his father's death. When this happens, we conclude that the man had been attached to his father with an especially strong love, and we remember how often a severe melancholia appears as a neurotic form of mourning.

¹ In the familiar fairy tale of 'The Seven Little Goats', the Father Wolf appears as a burglar.

² The fact that in our analyses we so seldom succeed in finding the Devil as a father-substitute may be an indication that for those who come to us for analysis this figure from mediaeval mythology has long since played out its part. For the pious Christian of earlier centuries belief in the Devil was no less a duty than belief in God. In point of fact, he needed the Devil in order to be able to keep hold of God. The later decrease in faith has, for various reasons, first and foremost affected the figure of the Devil.

If we are bold enough to apply this idea of the Devil as a father substitute to cultural history, we may also be able to see the witch-trials of the Middle Ages in a new light.

In this we are undoubtedly right. But we are not right if we conclude further that this relation has been merely one of love. On the contrary, his mourning over the loss of his father is the more likely to turn into melancholia, the more his attitude to him bore the stamp of ambivalence. This emphasis on ambivalence, however, prepares us for the possibility of the father being subjected to a debasement, as we see happening in the painter's demonological neurosis. If we were able to learn as much about Christoph Haizmann as about a patient undergoing an analysis with us, it would be an easy matter to elicit this ambivalence, to get him to remember when and under what provocations he was given cause to fear and hate his father; and, above all, to discover what were the accidental factors that were added to the typical motives for a hatred of the father which are necessarily inherent in the natural relationship of son to father. Perhaps we might then find a special explanation for the painter's inhibition in work. It is possible that his father had opposed his wish to become a painter. If that was so, his inability to practise his art after his father's death would on the one hand be an expression of the familiar phenomenon of 'deferred obedience'; and, on the other hand, by making him incapable of earning a livelihood, it would be bound to increase his longing for his father as a protector from the cares of life. In its aspect as deferred obedience it would also be an expression of remorse and a successful self-punishment.

Since, however, we cannot carry out an analysis of this sort with Christoph Haizmann, who died in the year 1700, we must content ourselves with bringing out those features of his case history which may point to the typical exciting causes of a negative attitude to the father. There are only a few such features, nor are they very striking, but they are of great interest.

Let us first consider the part played by the number nine. The pact with the Evil One was for nine years. On this point the unquestionably trustworthy report by the village priest of Pottenbrunn is quite clear: *pro novem annis Syngraphen scriptam tradidit*. This letter of introduction, dated September 1, 1677, is also able to inform us that the appointed time was about to expire in a few days: *quorum et finis 24 mensis hujus futurus appropinquat*. The pact would therefore have been signed on September 24, 1668.¹ In the same report, indeed, yet another use is made of the number nine. The painter claims to have withstood the temptations of the Evil One nine times - '*nonies*' - before he yielded to him. This detail is no longer mentioned in the later reports. In the Abbot's deposition the phrase '*pos annos novem*' is used, and the compiler repeats '*ad novem annos*' in his summary - a proof that this number was not regarded as indifferent.

¹ The contradictory fact that both the pacts as transcribed bear the date 1669 will be considered later.

The number nine is well known to us from neurotic phantasies. It is the number of the months of pregnancy, and wherever it appears it directs our attention to a phantasy of pregnancy. In our painter's case, to be sure, the number refers to years, not months; and it will be objected that nine is a significant number in other ways as well. But who knows whether it may not in general owe a good deal of its sanctity to the part it plays in pregnancy? Nor need we be disconcerted by the change from nine months to nine years. We know from dreams what liberties 'unconscious mental activity' takes with numbers. If, for instance, the number five occurs in a dream, this can invariably be traced back to a five that is important in waking life; but whereas in waking life the five was a five years' difference in age or a company of five people, it appeared in the dream as five bank-notes or five fruits. That is to say, the number is kept, but its denominator is changed according to the requirements of condensation and displacement. Nine years in a dream could thus easily correspond to nine months in real life. The dream-work plays about with the numbers of waking life in another way, too, for it shows a sovereign disregard for noughts and does not treat them as numbers at all. Five dollars in a dream can stand for fifty or five hundred or five thousand dollars in reality.

Another detail in the painter's relations to the Devil has once more a sexual reference. On the first occasion, as I have mentioned, he saw the Evil One in the shape of an honest citizen. But already on the second occasion the Devil was naked and misshapen, and had two pairs of female breasts. In none of his subsequent apparitions are the breasts absent, either as a single or a double pair. Only in one of them does the Devil exhibit, in addition to the breasts, a large penis ending in a snake. This stressing of the female sexual character by introducing large pendulous breasts (there is never any indication of the female genitals) is bound to appear to us as a striking contradiction of our hypothesis that the Devil had the meaning of a father-substitute for the painter. And, indeed, such a way of representing the Devil is in itself unusual. Where 'devil' is thought of in a generic sense, and devils appear in numbers, there is nothing strange about depicting female devils; but that *the* Devil, who is a great individuality, the Lord of Hell and the Adversary of God, should be represented otherwise than as a male, and, indeed, as a super-male, with horns, tail and a big penis-snake - this, I believe, is never found.

These two slight indications give us an idea of what the typical factor is which determines the negative side of the painter's relation to his father. What he is rebelling against is his feminine attitude to him which culminates in a phantasy of bearing him a child (the nine years). We have an accurate knowledge of this resistance from our analyses, where it takes on very strange forms in the transference and gives us a great deal of trouble. With the painter's mourning for his lost father, and the heightening of his longing for him, there also comes about in him a re-activation of his long-since repressed phantasy of pregnancy, and he is obliged to defend himself against it by a neurosis and by debasing his father.

But why should his father, after being reduced to the status of a Devil, bear this physical mark of a woman? The feature seems at first hard to interpret; but soon we find two explanations which compete with each other without being mutually exclusive. A boy's feminine attitude to his father undergoes repression as soon as he understands that his rivalry with a woman for his father's love has as a precondition the loss of his own male genitals - in other words, castration. Repudiation of the feminine attitude is thus the result of a revolt against castration. It regularly finds its strongest expression in the converse phantasy of castrating the father, of turning *him* into a woman. Thus the Devil's breasts would correspond to a projection of the subject's own femininity on to the father-substitute. The second explanation of these female additions to the Devil's body no longer has a hostile meaning but an affectionate one. It sees in the adoption of this shape an indication that the child's tender feelings towards his mother have been displaced on to his father; and this suggests that there has previously been a strong fixation on the mother, which, in its turn, is responsible for part of the child's hostility towards his father. Large breasts are the positive sexual characteristics of the mother even at a time when the negative characteristic of the female - her lack of a penis - is as yet unknown to the child.¹

¹ Cf. *Leonardo da Vinci and a Memory of his Childhood* (1910c).

If our painter's repugnance to accepting castration made it impossible for him to appease his longing for his father, it is perfectly understandable that he should have turned for help and salvation to the image of his mother. This is why he declared that only the Holy Mother of God of Mariazell could release him from his pact with the Devil and why he obtained his freedom once more on the day of the Mother's Nativity (September 8). Whether the day on which the pact was made - September 24 - was not also determined in some similar way, we shall of course never know.

Among the observations made by psycho-analysis of the mental life of children there is scarcely one which sounds so repugnant and unbelievable to a normal adult as that of a boy's feminine attitude to his father and the phantasy of pregnancy that arises from it. It is only since Senatspräsident Daniel Paul Schreber, a judge presiding over a division of the Appeal Court of Saxony, published the history of his psychotic illness and his extensive recovery from it,¹ that we can discuss the subject without trepidation or apology. We learn from this invaluable book that, somewhere about the age of fifty, the Senatspräsident became firmly convinced that God - who, incidentally, exhibited distinct traits of his father, the worthy physician, Dr. Schreber - had decided to emasculate him, to use him as a woman, and to beget from him 'a new race of men born from the spirit of Schreber'. (His own marriage was childless.) In his revolt against this intention of God's, which seemed to him highly unjust and 'contrary to the Order of Things', he fell ill with symptoms of paranoia, which, however, underwent a process of involution in the course of years, leaving only a small residue behind. The gifted author of his own case history could not have guessed that in it he had uncovered a typical pathogenic factor.

¹ *Denkwürdigkeiten eines Nervenkranken*, 1903. See my analysis of his case (1911c).

This revolt against castration or a feminine attitude has been torn out of its organic context by Alfred Adler. He has linked it superficially or falsely with the longing for power, and has postulated it as an independent 'masculine protest'. Since a neurosis can only arise from a conflict between two trends, it is as justifiable to see the cause of 'every' neurosis in the masculine protest as it is to see it in the feminine attitude against which the protest is being made. It is quite true that this masculine protest plays a regular part in the formation of character - in some types of people a very large part - and that we meet it in the analysis of neurotic men as a vigorous resistance. Psycho-analysis has attached due importance to the masculine protest in connection with the castration complex, without being able to accept its omnipotence or its omnipresence in neuroses. The most marked case of a masculine protest with all its manifest reactions and character-traits that I have met with in analysis was that of a patient who came to me for treatment on account of an obsessional neurosis in whose symptoms the unresolved conflict between a masculine and a feminine attitude (fear of castration and desire for castration) found clear expression. In addition, the patient had developed masochistic phantasies which were wholly derived from a wish to accept castration; and he had even gone beyond these phantasies to real satisfaction in perverse situations. The whole of his state rested - like Adler's theory itself - on the repression and denial of early infantile fixations of love.

Senatspräsident Schreber found the way to recovery when he decided to give up his resistance to castration and to accommodate himself to the feminine role cast for him by God. After this, he became lucid and calm, was able to put through his own discharge from the asylum and led a normal life - with the one exception that he devoted some hours every day to the cultivation of his femaleness, of whose gradual advance towards the goal determined by God he remained convinced.

IV

THE TWO BONDS

A remarkable detail in our painter's story is the statement that he signed two different bonds with the Devil. The first, written in black ink, ran as follows:

'I, Chr. H., subscribe myself to this Lord as his bounden son till the ninth year.'

The second, written in blood, ran:

'Chr. H. I sign a bond with this Satan, to be his bounden son, and in the ninth year to belong to him body and soul.'

The originals of both are said to have been in the archives at Mariazell when the *Trophaeum* was compiled, and both bear the same date - 1669.

I have already made a number of references to the two bonds; and I now propose to deal with them in greater detail, although it is precisely here that the danger of overvaluing trifles seems especially great.

It is unusual for anyone to sign a bond with the Devil twice, in such a way that the first document is replaced by the second, but without losing its own validity. Perhaps this occurrence is less surprising to other people, who are more at home with demonological material. For my part, I could only look on it as a special peculiarity of our case, and my suspicions were aroused when I found that the reports were at variance precisely on this point. Examination of these discrepancies will afford us, unexpectedly, a deeper understanding of the case history.

The village priest of Pottenbrunn's letter of introduction describes a very simple and clear situation. In it mention is only made of one bond, which was written in blood by the painter nine years before and which was due to expire in a few days' time - on September 24. It must therefore have been drawn up on September 24, 1668; unfortunately this date, although it can be inferred with certainty, is not explicitly stated.

The Abbot Franciscus's deposition, which was dated, as we know, a few days later (September 12, 1677), already describes a more complicated state of affairs. It is plausible to assume that the painter had given more precise information in the interval. The deposition relates that the painter had signed two bonds: one in the year 1668 (a date which should also be the correct one according to the letter of introduction), written in black ink, and the other '*sequenti anno 1669*', written in blood. The bond that he received back on the day of the Nativity of the Virgin was the one written in blood - viz. the later bond, which had been signed in 1669. This does not emerge from the Abbot's deposition, for there it merely says later '*schedam redderet*' and '*schedam sibi porrigentem conspexisset*' as if there could only be a single document in question. But it does follow from the subsequent course of the story, and also from the coloured title-page of the *Tropheaum*, where what is clearly a *red* script can be seen on the paper which the demon dragon is holding. The further course of the story is, as I have already related, that the painter returned to Mariazell in May, 1678, after he had experienced further temptations from the Evil One in Vienna; and that he begged that, through a further act of Grace on the part of the Holy Mother, the first document, written in ink, might also be given back to him. In what way this came about is not so fully described as on the first occasion. We are merely told: '*quâ juxta votum redditâ*'; and in another passage the compiler says that this particular bond was thrown to the painter by the Devil 'crumpled up and torn into four pieces' on May 9, 1678, at about nine o'clock in the evening.

Both bonds, however, bear the date of the same year - 1669.

This incompatibility is either of no significance or may put us on the following track.

If we take as a starting-point the Abbot's account, as being the more detailed one, we are confronted with a number of difficulties. When Christoph Haizmann confessed to the village priest of Pottenbrunn that he was hard pressed by the Devil and that the time-limit would soon run out, he could only (in 1677) have been thinking of the bond which he had signed in 1668 - namely, the first one, written in black (which is referred to in the letter of introduction as the only one, but is described there being written in blood). But a few days later, at Mariazell, he was only concerned to get back the later bond, in blood, which was not nearly due to expire then (1669-77), and allowed the first one to become overdue. This latter was not reclaimed till 1678 - that is, when it had run into its tenth year. Furthermore, why are both the bonds dated in the same year (1669), when one of them is explicitly attributed to the following year ('*anno subsequenti*')?

The compiler must have noticed these difficulties, for he made an attempt to remove them. In his preface he adopted the Abbot's version, but he modified it in one particular. The painter, he says, signed a bond with the Devil in 1669 in ink, but afterwards ('*deinde vero*') in blood. He thus overrode the express statement of both reports that one bond was signed in 1668, and he ignored the Abbot's remark in his deposition to the effect that there was a difference in the year-number between the two bonds. This he did in order to keep in harmony with the dating of the two documents that were given back by the Devil.

In the Abbot's deposition a passage appears in brackets after the words '*sequenti vero anno 1669*'. It runs: '*sumitur hic alter annus pro nondum completo, uti saepe in loquendo fieri solet, nam eundem annum indicant syngraphae, quarum atramento scripta ante praesentem attestationem nondum habita fuit.*' This passage is clearly an interpolation by the compiler; for the Abbot, who had only seen one bond, could not have stated that both bore the same date. The placing of the passage in brackets, moreover, must have been intended to show that it was an addition to the text of the deposition. It represents another attempt on the compiler's part to reconcile the incompatible evidence. He agrees that the first bond was signed in 1668; but he thinks that, since the year was already far advanced (it was September), the painter had post-dated it by a year so that both bonds were able to show the same year. His invoking the fact that people often do the same sort of thing in conversation seems to me to stamp his whole attempt at an explanation as no more than a feeble evasion.

I cannot tell whether my presentation of the case has made any impression on the reader and whether it has put him in a position to take an interest in these minute details. I myself have found it impossible to arrive with any certainty at the true state of affairs; but, in studying this confused business, I hit upon a notion which has the advantage of giving the most natural picture of the course of events, even though once more the written evidence does not entirely fit in with it.

My view is that when the painter first came to Mariazell he spoke only of one bond, written in the regular way in blood, which was about to fall due and which had therefore been signed in September, 1668 - all exactly as described in the village priest's letter of introduction. In Mariazell, too, he presented this bond in blood as the one which the Demon had given back to him under compulsion from the Holy Mother. We know what happened subsequently. The painter left the shrine soon afterwards and went to Vienna, where he felt free till the middle of October. Then, however, he began once more to be subjected to sufferings and apparitions, in which he saw the work of the Evil Spirit. He again felt in need of redemption, but was faced with the difficulty of explaining why the exorcism in the holy Chapel had not brought him a lasting deliverance. He would certainly not have been welcome at Mariazell if he had returned there uncured and relapsed. In this quandary, he invented an earlier, first bond, which, however, was to be written in ink, so that its supersession in favour of a later bond, written in blood, should seem more plausible. Having returned to Mariazell, he had this alleged first bond given back to him too. After this he was left in peace by the Evil One; but at the same time he did something else, which will show us what lay in the background of his neurosis.

The drawings he made were undoubtedly executed during his second stay at Mariazell: the title-page, which is a single composition, contains a representation of both the bond scenes. The attempt to make his new story tally with his earlier one may well have caused him embarrassment. It was unfortunate for him that his additional invention could only be of an earlier bond and not of a later one. Thus he could not avoid the awkward result that he had redeemed one - the blood bond - too soon (in the eighth year), and the other - the black bond - too late (in the tenth year). And he betrayed the double editing of the story by making a mistake in the dating of the bonds and attributing the earlier one as well as the later to the year 1669. This mistake has the significance of a piece of unintentional honesty: it enables us to guess that the supposedly earlier bond was fabricated at the later date. The compiler, who certainly did not begin revising the material before 1714, and perhaps not till 1729, had to do his best to resolve its not inconsiderable contradictions. Finding that both the bonds before him were dated 1669, he had recourse to the evasion which he interpolated in the Abbot's deposition.

It is easy to see where the weak spot lies in this otherwise attractive reconstruction. Reference is already made to the existence of two bonds, one in black and one in blood, in the Abbot's deposition. I therefore have the choice between accusing the compiler of having also made an alteration in the deposition, an alteration closely related to his interpolation, or confessing that I am unable to unravel the tangle.¹

¹ The compiler, it seems to me, was between two fires. On the one hand, he found, in the village priest's letter of introduction as well as in the Abbot's deposition, the statement that the bond (or at any rate the first bond) had been signed in 1668; on the other hand, both bonds, which had been preserved in the archives, bore the date 1669. As he had two bonds before him, it seemed certain to him that two bonds had been signed. If, as I believe, the Abbot's deposition mentioned only one bond, he was obliged to insert in the deposition a reference to the other and then remove the contradiction by the hypothesis of the post-dating. The textual alteration which he made occurs immediately before the interpolation, which can only have been written by him. He was obliged to link the interpolation to the alteration with the words '*sequenti vero anno 1669*', since the painter had expressly written in his (very much damaged) caption to the title-page:

'A year after He
... terrible threatenings in
... shape No. 2, was forced
... to sign a bond in blood.'

The painter's blunder in writing his *Syngraphae* - a blunder which I have been obliged to assume in my attempted explanation - appears to me to be no less interesting than are the actual bonds.

The reader will long ago have judged this whole discussion superfluous and the details concerned in it too unimportant. But the matter gains a new interest if it is pursued in a certain direction.

I have just expressed the view that, when the painter was disagreeably surprised by the course taken by his illness, he invented an earlier bond (the one in ink) in order to be able to maintain his position with the reverend Fathers at Mariazell. Now I am writing for readers who, although they believe in psycho-analysis, do not believe in the Devil; and they might object that it was absurd for me to bring such an accusation against the poor wretch - *hunc miserum*, as he is called in the letter of introduction. For, they will say, the bond in blood was just as much a product of his phantasy as the allegedly earlier one in ink. In reality, no Devil appeared to him at all, and the whole business of pacts with the Devil only existed in his imagination. I quite realize this: the poor man cannot be denied the right to supplement his original phantasy with a new one, if altered circumstances seem to require it.

But here, too, the matter goes further. After all, the two bonds were not phantasies like the visions of the Devil. They were documents, preserved, according to the assurances of the copyist and the deposition of the later Abbot Kilian, in the archives of Mariazell, for all to see and touch. We are therefore in a dilemma. Either we must assume that both the papers which were supposed to have been given back to the painter through divine Grace were written by him at the time when he needed them; or else, despite all the solemn assurances, the confirmatory evidence of witnesses, signed and sealed, and so on, we shall be obliged to deny the credibility of the reverend Fathers of Mariazell and St. Lambert. I must admit that I am unwilling to cast doubts on the Fathers. I am inclined to think, it is true, that the compiler, in the interests of consistency, has falsified some things in the deposition made by the first Abbot; but a 'secondary revision' such as this does not go much beyond what is carried out even by modern lay historians, and at all events it was done in good faith. In another respect, the reverend Fathers have established a good claim to our confidence. As I have said already there was nothing to prevent them from suppressing the accounts of the incompleteness of the cure and the continuance of the temptations. And even the description of the scene of exorcism in the Chapel, which one might have viewed with some apprehension, is soberly written and inspires belief. So there is nothing for it but to lay the blame on the painter. No doubt he had the red bond with him when he went to penitential prayer in the Chapel, and he produced it afterwards as he came back to his spiritual assistants from his meeting with the Demon. Nor need it have been the same paper which was later preserved in the archives, and, according to our construction, it may have borne the date 1668 (nine years before the exorcism).

V

THE FURTHER COURSE OF THE NEUROSIS

But if this is so, we should be dealing not with a neurosis but with a deception, and the painter would be a malingerer and forger instead of a sick man suffering from possession. But the transitional stages between neurosis and malingering are, as we know, very fluid. Nor do I see any difficulty in supposing that the painter wrote this paper and the later one, and took them with him, in a peculiar state, similar to the one in which he had his visions. Indeed there was no other course open to him if he wished to carry into effect his phantasy of his pact with the Devil and of his redemption.

On the other hand, the diary written in Vienna, which he gave to the clerics on his second visit to Mariazell, bears the stamp of veracity. It undoubtedly affords us a deep insight into the motivation - or let us rather say, the exploitation - of the neurosis.

The entries extend from the time of the successful exorcism till January 13 of the following year, 1678.

Until October 11 he felt very well in Vienna, where he lived with a married sister; but after that he had fresh attacks, with visions, convulsions, loss of consciousness and painful sensations, and these finally led to his return to Mariazell in May, 1678.

The story of his fresh illness falls into three phases. First, temptation appeared in the form of a finely dressed cavalier, who tried to persuade him to throw away the document attesting his admission to the Brotherhood of the Holy Rosary. He resisted this temptation, whereupon the same thing happened next day; only this time the scene was laid in a magnificently decorated hall in which grand gentlemen were dancing with beautiful ladies. The same cavalier who had tempted him before made a proposal to him connected with painting¹ and promised to give him a handsome sum of money in return. After he had made this vision disappear by prayer, it was repeated once more a few days later, in a still more pressing form. This time the cavalier sent one of the most beautiful of the ladies who sat at the banqueting table to him to persuade him to join their company, and he had difficulty in defending himself from the temptress. Most terrifying of all, moreover, was the vision which occurred soon after this. He saw a still more magnificent hall, in which there was a 'throne built up of gold pieces'. Cavaliers were standing about awaiting the arrival of their King. The same person who had so often made proposals to him now approached him and summoned him to ascend the throne, for they 'wanted to have him for their King and to honour him for ever'. This extravagant phantasy concluded the first, perfectly transparent, phase of the story of his temptation.

¹ This passage is unintelligible to me.

There was bound to be a revulsion against this. An ascetic reaction reared its head. On October 20 a great light appeared, and a voice came from it, making itself known as Christ, and commanded him to forswear this wicked world and serve God in the wilderness for six years. The painter clearly suffered more from these holy apparitions than from the earlier demoniacal ones; it was only after two and a half hours that he awoke from this attack. In the next attack the holy figure surrounded by light was much more unfriendly. He issued threats against him for not having obeyed the divine behest and led him down into Hell so that he might be terrified by the fate of the damned. Evidently, however, this failed in its effect, for the apparitions of the figure surrounded by light, which purported to be Christ, were repeated several more times. Each time the painter underwent an *absence* and an ecstasy lasting for hours. In the grandest of these ecstasies the figure surrounded by light took him first into a town in whose streets people were perpetrating all the acts of darkness; and then, in contrast, took him to a lovely meadow in which anchorites were leading a godly life and were receiving tangible evidence of God's grace and care. There then appeared, instead of Christ, the Holy Mother herself, who, reminding him of what she had already done on his behalf, called on him to obey the command of her dear Son. 'Since he could not truly resolve so to do', Christ appeared to him again the next day and upbraided him soundly with threats and promises. At last he gave way and made up his mind to leave the world and to do what was required of him. With this decision, the second phase ended. The painter states that from this time onwards he had no more visions and no more temptations.

Nevertheless, his resolution cannot have been firm enough or he must have delayed its execution too long; for while he was in the midst of his devotions, on December 26, in St. Stephen's, catching sight of a strapping young woman accompanied by a smartly dressed gentleman, he could not fend off the thought that he might himself be in this gentleman's place. This called for punishment, and that very evening it overtook him like a thunderbolt. He saw himself in bright flames and sank down in a swoon. Attempts were made to rouse him but he rolled about in the room till blood flowed from his mouth and nose. He felt that he was surrounded by heat and noisome smells, and he heard a voice say that he had been condemned to this state as a punishment for his vain and idle thoughts. Later he was scourged with ropes by Evil Spirits, and was told that he would be tormented like this every day until he had decided to enter the Order of Anchorites. These experiences continued up to the last entry in his diary (January 13).

We see how our unfortunate painter's phantasies of temptation were succeeded by ascetic ones and finally by phantasies of punishment. The end of his tale of suffering we know already. In May he went to Mariazell, told his story of an earlier bond written in black ink, to which he explicitly attributed his continued torment by the Devil, received this bond back, too, and was cured.

During his second stay there he painted the pictures which are copied in the *Trophaeum*. Then he took a step which was in keeping with the demands of the ascetic phase of his diary. He did not, it is true, go into the wilderness to become an anchorite, but he joined the Order of the Brothers Hospitallers: *religiosus factus est*.

Reading the diary, we gain insight into another part of the story. It will be remembered that the painter signed a bond with the Devil because after his father's death, feeling depressed and unable to work, he was worried about making a livelihood. These factors of depression, inhibition in his work and mourning for his father are somehow connected with one another, whether in a simple or a complicated way. Perhaps the reason why the apparitions of the Devil were so over-generously furnished with breasts was that the Evil One was meant to become his foster father. This hope was not fulfilled, and the painter continued to be in a bad state. He could not work properly, or he was out of luck and could not find enough employment. The village priest's letter of introduction speaks of him as '*hunc miserum omni auxilio destitutum*'. He was thus not only in moral straits but was suffering material want. In the account of his later visions, we find remarks here and there indicating - as do the contents of the scenes described - that even after the successful first exorcism, nothing had been changed in his situation. We come to know him as a man who fails in everything and who is therefore trusted by no one. In his first vision the cavalier asked him 'what he is going to do, since he has no one to stand by him'. The first series of visions in Vienna tallied completely with the wishful phantasies of a poor man, who had come down in the world and who hungered for enjoyment: magnificent halls, high living, a silver dinner-service and beautiful women. Here we find what was missing in his relations with the Devil made good. At that time he had been in a melancholia which made him unable to enjoy anything and obliged him to reject the most attractive offers. After the exorcism the melancholia seems to have been overcome and all his worldly-minded desires had once more become active.

In one of the ascetic visions he complained to his guide (Christ) that nobody had any faith in him, so that he was unable to carry out the commands laid upon him. The reply he was given is, unfortunately, obscure to us: 'Although they will not believe me, yet I know well what has happened, but I am not able to declare it.' Especially illuminating, however, are the experiences which his heavenly Guide made him have among the anchorites. He came to a cave in which an old man had been sitting for the last sixty years, and in answer to a question he learnt that this old man had been fed every day by God's angels. And then he saw for himself how an angel brought the old man food: 'Three dishes with food, a loaf, a dumpling and some drink.' After the anchorite had eaten, the angel collected everything and carried it away. We can see what the temptation was which the pious visions offered the painter: they were meant to induce him to adopt a mode of existence in which he need no longer worry about sustenance. The utterances of Christ in the last vision are also worthy of note. After threatening that, if he did not prove amenable, something would happen which would oblige him and the people to believe [in it], Christ gave him a direct warning that 'I should not heed the people; even if they were to persecute me or give me no help, God would not abandon me'.

Christoph Haizmann was enough of an artist and a child of the world to find it difficult to renounce this sinful world. Nevertheless, in view of his helpless position, he did so in the end. He entered a Holy Order. With this, both his internal struggle and his material need came to an end. In his neurosis, this outcome was reflected in the fact of his seizures and visions being brought to an end by the return of an alleged first bond. Actually, both portions of his demonological illness had the same meaning. He wanted all along simply to make his life secure. He tried first to achieve this with the help of the Devil at the cost of his salvation; and when this failed and had to be given up, he tried to achieve it with the help of the clergy at the cost of his freedom and most of the possibilities of enjoyment in life. Perhaps he himself was only a poor devil who simply had no luck; perhaps he was too ineffective or too untalented to make a living, and was one of those types of people who are known as 'eternal sucklings' - who cannot tear themselves away from the blissful situation at the mother's breast, and who, all through their lives, persist in a demand to be nourished by someone else. - And so it was that, in this history of his illness, he followed the path which led from his father, by way of the Devil as a father substitute, to the pious Fathers of the Church.

To superficial observation Haizmann's neurosis appears to be a masquerade which overlays a part of the serious, if commonplace, struggle for existence. This is not always the case, but it is not infrequently so. Analysts often discover how unprofitable it is to treat a business man who 'though otherwise in good health, has for some time shown signs of a neurosis'. The business catastrophe with which he feels himself threatened throws up the neurosis as a by-product; and this gives him the advantage of being able to conceal his worries about his real life behind his symptoms. But apart from this the neurosis serves no useful purpose whatever, since it uses up forces which would have been more profitably employed in dealing rationally with the dangerous situation.

In a far greater number of cases the neurosis is more autonomous and more independent of the interests of self-preservation and self-maintenance. In the conflict which creates the neurosis, what are at stake are either solely libidinal interests or libidinal interests in intimate connections with self-preservative ones. In all three instances the dynamics of the neurosis are the same. A dammed-up libido which cannot be satisfied in reality succeeds, with the help of a regression to old fixations, in finding discharge through the repressed unconscious. The sick man's ego, in so far as it can extract a 'gain from illness' out of this process, countenances the neurosis, although there can be no doubt of its injuriousness in its economic aspect.

Nor would our painter's wretched situation in life have provoked a demonological neurosis in him if his material need had not intensified his longing for his father. After his melancholia and the Devil had been disposed of, however, he still had to face a struggle between his libidinal enjoyment of life and his realization that the interests of self-preservation called imperatively for renunciation and asceticism. It is interesting to see that the painter was very well aware of the unity of the two portions of his illness, for he attributed both to the bonds which he had signed with the Devil. On the other hand, he made no sharp distinction between the operations of the Evil Spirit and those of the Divine Powers. He had only one description for both: they were manifestations of the Devil.

REMARKS ON THE THEORY AND PRACTICE OF DREAM-INTERPRETATION
(1923)

Intentionally left blank

REMARKS ON THE THEORY AND PRACTICE OF DREAM-INTERPRETATION

The accidental circumstance that the last editions of my *Interpretation of Dreams* (1900a) have been printed from stereotype plates has led me to issue the following remarks in an independent form, instead of introducing them into the text as modifications or additions.

I

In interpreting a dream during an analysis a choice lies open to one between several technical procedures.

One can (a) proceed chronologically and get the dreamer to bring up his associations to the elements of the dream in the order in which those elements occurred in his account of the dream. This is the original, classical method, which I still regard as the best if one is analysing one's own dreams.

Or one can (b) start the work of interpretation from some one particular element of the dream which one picks out from the middle of it. For instance, one can choose the most striking piece of it, or the piece which shows the greatest clarity or sensory intensity; or, again, one can start off from some spoken words in the dream, in the expectation that they will lead to the recollection of some spoken words in waking life.

Or one can (c) begin by entirely disregarding the manifest content and instead ask the dreamer what events of the previous day are associated in his mind with the dream he has just described.

Finally, one can (d), if the dreamer is already familiar with the technique of interpretation, avoid giving him any instructions and leave it to him to decide with which associations to the dream he shall begin.

I cannot lay it down that one or the other of these techniques is preferable or in general yields better results.

II

What is of far greater importance is the question of whether the work of interpretation proceeds under a *pressure of resistance* which is *high* or *low* - a point on which the analyst never remains long in doubt. If the pressure is high, one may perhaps succeed in discovering what the things are with which the dream is concerned, but one cannot make out what it says about these things. It is as though one were trying to listen to a conversation taking place at a distance or in a very low voice. In that case, one can feel confident that there is not much prospect of collaborating with the dreamer, one decides not to bother too much about it and not to give him much help, and one is content to put before him a few translations of symbols that seem probable.

The majority of dreams in a difficult analysis are of this kind; so that one cannot learn much from them about the nature and mechanism of dream-formation. Least of all can one learn anything from them upon the recurring question of where the dream's wish-fulfilment may lie hidden. When the pressure of resistance is quite extremely high, one meets with the phenomenon of the dreamer's associations broadening instead of deepening. In place of the desired associations to the dream that has already been narrated, there appear a constant succession of new fragments of dream, which in their turn remain without associations.

It is only when the resistance is kept within moderate limits that the familiar picture of the work of interpretation comes into view: the dreamer's associations begin by *diverging* widely from the manifest elements, so that a great number of subjects and ranges of ideas are touched on, after which, a second series of associations quickly *converge* from these on to the dream-thoughts that are being looked for. When this is so, collaboration between the analyst and the dreamer becomes possible; whereas under a high pressure of resistance it would not even be of any advantage.

A number of dreams which occur during analyses are untranslatable even though they do not actually make much show of the resistance that is there. They represent free renderings of the latent dream-thoughts behind them and are comparable to successful creative writings which have been artistically worked over and in which the basic themes are still recognizable though they have been subjected to any amount of re-arrangement and transformation. Dreams of this kind serve in the treatment as an introduction to thoughts and memories of the dreamer without their own actual content coming into account.

III

It is possible to distinguish between dreams *from above* and dreams *from below*, provided the distinction is not made too sharply. Dreams from below are those which are provoked by the strength of an unconscious (repressed) wish which has found a means of being represented in some of the day's residues. They may be regarded as inroads of the repressed into waking life. Dreams from above correspond to thoughts or intentions of the day before which have contrived during the night to obtain reinforcement from repressed material that is debarred from the ego. When this is so, analysis as a rule disregards this unconscious ally and succeeds in inserting the latent dream-thoughts into the texture of waking thought. This distinction calls for no modification in the theory of dreams.

IV

In some analyses, or in some periods of an analysis, a divorce may become apparent between dream-life and waking life, like the divorce between the activity of phantasy and waking life which is found in the 'continued story' (a novel in day-dreams). In that case one dream leads off from another, taking as its central point some element which was lightly touched upon in its predecessor, and so on. But we find far more frequently that dreams are not attached to one another but are interpolated into a successive series of portions of waking thought.

V

The interpretation of a dream falls into two phases: the phase in which it is translated and the phase in which it is judged or has its value assessed. During the first phase one must not allow oneself to be influenced by any consideration whatever for the second phase. It is as though one had before one a chapter from some work in a foreign language - by Livy, for instance. The first thing one wants to know is what Livy says in the chapter; and it is only after this that the discussion arises of whether what one has read is a historical narrative or a legend or a digression on the part of the author.

What conclusions can one draw from a correctly translated dream? I have an impression that analytic practice has not always avoided errors and over-estimations on this point, partly owing to an exaggerated respect for the 'mysterious unconscious'. It is only too easy to forget that a dream is as a rule merely a thought like any other, made possible by a relaxation of the censorship and by unconscious reinforcement, and distorted by the operation of the censorship and by unconscious revision.

Let us take as an example the so-called dreams of recovery. If a patient has had a dream of this kind, in which he seems to abandon the restrictions of his neurosis - if, for instance, he overcomes some phobia or gives up some emotional attachment - we are inclined to think that he has made a great step forward, that he is ready to take his place in a new state of life, that he has begun to reckon on his recovery, etc. This may often be true, but quite as often such dreams of recovery only have the value of dreams of convenience: they signify a wish to be well at last, in order to avoid another portion of the work of analysis which is felt to lie ahead. In this sense, dreams of recovery very frequently occur, for instance, when the patient is about to enter upon a new and disagreeable phase of the transference. He is behaving in this just like some neurotics who after a few hours of analysis declare they have been cured - because they want to escape all the unpleasantness that is bound to come up for discussion in the analysis. Sufferers from war neuroses, too, who gave up their symptoms because the therapy adopted by the army doctors succeeded in making being ill even more uncomfortable than serving at the front - these sufferers, too, were following the same economic laws and in both cases alike the cures have proved to be only temporary.

VI

It is by no means easy to arrive at general conclusions upon the value of correctly translated dreams. If a conflict due to ambivalence is taking place in a patient, then the emergence in him of a hostile thought certainly does not imply a permanent overcoming of his affectionate impulse - that is to say, a resolution of the conflict: neither does any such implication follow from a *dream* with a similarly hostile content. During a conflict such as this arising from ambivalence, there are often two dreams every night, each of them representing an opposite attitude. In that case the progress lies in the fact that a complete isolation of the two contrasted impulses has been achieved and that each of them, with the help of its unconscious reinforcements, can be followed and understood to its extreme limits. And if it sometimes happens that one of the two ambivalent dreams has been forgotten, one must not be deceived into assuming that a decision has been made in favour of the one side. The fact that one of the dreams has been forgotten shows, it is true, that for the moment one tendency is in the ascendant, but that is true only of the one day, and may be changed. The next night may perhaps bring the opposite expression into the foreground. The true state of the conflict can only be determined by taking into account all the other indications, including those of waking life.

VII

The question of the value to be assigned to dreams is intimately related to the other question of their susceptibility to influence from 'suggestion' by the physician. Analysts may at first be alarmed at the mention of this possibility. But on further reflection this alarm will give place to the realization that the influencing of the patient's dreams is no more a blunder on the part of the analyst or disgrace to him than the guiding of the patient's conscious thoughts.

The fact that the manifest content of dreams is influenced by the analytic treatment stands in no need of proof. It follows from our knowledge that dreams take their start from waking life and work over material derived from it. Occurrences during analytic treatment are of course among the impressions of waking life and soon become some of the most powerful of these. So it is not to be wondered at that patients should dream of things which the analyst has discussed with them and of which he has aroused expectations in them. At least it is no more to be wondered at than what is implied in the familiar fact of 'experimental' dreams.

But from here our interest proceeds to the question whether the latent dream-thoughts that have to be arrived at by interpretation can also be influenced or suggested by the analyst. And to this the answer must once more be that they obviously can be. For a portion of these latent dream-thoughts correspond to preconscious thought-formations, perfectly capable of being conscious, with which the dreamer might quite well have reacted to the physician's remarks in his waking state too - whether the patient's reactions were in harmony with those remarks or in opposition to them. In fact, if we replace the dream by the dream-thoughts which it contains, the question of how far one can suggest dreams coincides with the more general question of how far a patient in analysis is accessible to suggestion.

On the mechanism of dream-formation itself, on the dream-work in the strict sense of the word, one never exercises any influence: of that one may be quite sure.

Besides that portion of the dream which we have already discussed - the preconscious dream-thoughts - every true dream contains indications of the repressed wishful impulses to which it owes the possibility of its formation. The doubter will reply that they appear in the dream because the dreamer knows that he ought to produce them - that they are expected by the analyst. The analyst himself will rightly think otherwise.

If a dream brings up situations that can be interpreted as referring to scenes from the dreamer's past, it seems especially important to ask whether the physician's influence can also play a part in such contents of the dream as these. And this question is most urgent of all in the case of what are called 'corroborative' dreams, dreams which, as it were, 'tag along behind' the analysis. With some patients these are the only dreams that one obtains. Such patients reproduce the forgotten experiences of their childhood only after one has constructed them from their symptoms, associations and other signs and has propounded these constructions to them. Then follow the corroborative dreams, concerning which, however, the doubt arises whether they may not be entirely without evidential value, since they may have been imagined in compliance with the physician's words instead of having been brought to light from the dreamer's unconscious. This ambiguous position cannot be escaped in the analysis, since with these patients unless one interprets, constructs and propounds, one never obtains access to what is repressed in them.

The situation takes a favourable turn if the analysis of a corroborative dream of this sort, which 'tags along behind', is immediately followed by feelings of remembering what has hitherto been forgotten. But even then the sceptic can fall back upon an assertion that the recollections are illusory. Moreover, such feelings are for the most part absent. The repressed material is only allowed through bit by bit; and every lack of completeness inhibits or delays the forming of a sense of conviction. Furthermore, what we are dealing with may not be the reproduction of a real and forgotten event but the bringing forward of an unconscious phantasy, about which no feeling of memory is ever to be expected, though the possibility may sometimes remain of a sense of subjective conviction.

Is it possible, then, that corroborative dreams are really the result of suggestion, that they are 'obliging' dreams? The patients who produce only corroborative dreams are the same patients in whom doubt plays the principal part in resistance. One makes no attempt at shouting down this doubt by means of one's authority or at reducing it by arguments. It must persist until it is brought to an end in the further course of the analysis. The analyst, too, may himself retain a doubt of the same kind in some particular instances. What makes him certain in the end is precisely the complication of the problem before him, which is like the solution of a jig-saw puzzle. A coloured picture, pasted upon a thin sheet of wood and fitting exactly into a wooden frame, is cut into a large number of pieces of the most irregular and crooked shapes. If one succeeds in arranging the confused heap of fragments, each of which bears upon it an unintelligible piece of drawing, so that the picture acquires a meaning, so that there is no gap anywhere in the design and so that the whole fits into the frame - if all these conditions are fulfilled, then one knows that one has solved the puzzle and that there is no alternative solution.

An analogy of this kind can of course have no meaning for a patient while the work of analysis is still uncompleted. At this point I recall a discussion which I was led into with a patient whose exceptionally ambivalent attitude was expressed in the most intense compulsive doubt. He did not dispute my interpretations of his dreams and was very much struck by their agreement with the hypotheses which I put forward. But he asked whether these corroborative dreams might not be an expression of his compliance towards me. I pointed out that the dreams had also brought up a quantity of details of which I could have had no suspicion and that his behaviour in the treatment apart from this had not been precisely characterized by compliance. Whereupon he switched over to another theory and asked whether his narcissistic wish to be cured might not have caused him to produce these dreams, since, after all, I had held out to him a prospect of recovery if he were able to accept my constructions. I could only reply that I had not yet come across any such mechanism of dream-formation. But a decision was reached by another road. He recollected some dreams which he had had before starting analysis and indeed before he had known anything about it; and the analysis of these dreams, which were free from all suspicion of suggestion, led to the same interpretations as the later ones. It is true that his obsession for contradiction once more found a way out in the idea that the earlier dreams had been less clear than those that occurred during the treatment; but I was satisfied with their similarity. I think that in general it is a good plan occasionally to bear in mind the fact that people were in the habit of dreaming before there was such a thing as psycho-analysis.

VIII

It may well be that dreams during psycho-analysis succeed in bringing to light what is repressed to a greater extent than dreams outside that situation. But it cannot be proved, since the two situations are not comparable; the employment of dreams in analysis is something very remote from their original purpose. On the other hand, it cannot be doubted that within an analysis far more of the repressed is brought to light in connection with dreams than by any other method. In order to account for this, there must be some motive power, some unconscious force, which is better able to lend support to the purposes of analysis during the state of sleep than at other times. What is here in question cannot well be any factor other than the patient's compliance towards the analyst which is derived from his parental complex - in other words, the positive portion of what we call the transference; and in fact, in many dreams which recall what has been forgotten and repressed, it is impossible to discover any other unconscious wish to which the motive force for the formation of the dream can be attributed. So that if anyone wishes to maintain that most of the dreams that can be made use of in analysis are obliging dreams and owe their origin to suggestion, nothing can be said against that opinion from the point of view of analytic theory. In that case I need only add a reference to what I have said in my *Introductory Lectures*, where I have dealt with the relation between transference and suggestion and shown how little the trustworthiness of our results is affected by a recognition of the operation of suggestion in our sense.

In *Beyond the Pleasure Principle* (1920g) I have dealt with the economic problem of how what are in every respect distressing experiences of the early infantile sexual period can succeed in forcing their way through to some kind of reproduction. I was obliged to ascribe to them an extraordinarily strong upward drive in the shape of the 'compulsion to repeat' - a force able to overcome the repression which, in obedience to the pleasure principle, weighs down upon them - though not until 'the work of treatment has gone half-way to meet it and has loosened the repression'. Here we may add that it is the positive transference that gives this assistance to the compulsion to repeat. Thus an alliance has been made between the treatment and the compulsion to repeat, an alliance which is directed in the first instance against the pleasure principle but of which the ultimate purpose is the establishment of the dominion of the reality principle. As I have shown in the passage to which I am referring, it happens only too often that the compulsion to repeat throws over its obligations under this alliance and is not content with the return of the repressed merely in the form of dream-pictures.

IX

So far as I can at present see, dreams that occur in a traumatic neurosis are the only *genuine* exceptions, and punishment dreams are the only *apparent* exceptions, to the rule that dreams are directed towards wish-fulfilment. In the latter class of dreams we are met by the remarkable fact that actually nothing belonging to the latent dream-thoughts is taken up into the manifest content of the dream. Something quite different appears instead, which must be described as a reaction-formation against the dream-thoughts, a rejection and complete contradiction of them. Such offensive action as this against the dream can only be ascribed to the critical agency of the ego and it must therefore be assumed that the latter, provoked by the unconscious wish-fulfilment, has been temporarily re-established even during the sleeping state. It might have reacted to the undesirable content of the dream by waking up; but it has found a means, by the construction of the punishment dream, of avoiding an interruption of sleep.

For instance, in the case of the well-known dreams of the poet Rosegger which I discussed in *The Interpretation of Dreams*, we must suspect the existence of a suppressed version with an arrogant and boastful text, whereas the actual dream said to him: 'You are an incompetent journeyman tailor.' It would, of course, be useless to look for a repressed wishful impulse as the motive power for a manifest dream such as this; one must be content with the fulfilment of the wish for self-criticism.

A dream-structure of this kind will excite less astonishment if one considers how frequently dream-distortion, acting in the service of the censorship, replaces a particular element by something that is in some sense or other its opposite or contrary. It is only a short step from there to the replacement of a characteristic portion of the content of the dream by a defensive contradiction, and one further step will lead to the whole objectionable dream-content being replaced by the punishment dream. I should like to give a couple of characteristic examples of the intermediate phase in the falsification of the manifest content.

Here is an extract from the dream of a girl with a strong fixation to her father, who had difficulty in talking during the analysis. She was sitting in a room with a girl friend, and dressed only in a kimono. A gentleman came in and she felt embarrassed. But the gentleman said: 'Why, this is the girl we saw once before dressed so nicely!' - The gentleman stood for me, and, further back, for her father. But we can make nothing of the dream unless we make up our mind to replace the most important element in the gentleman's speech by its contrary: 'This is the girl I saw once before *undressed* and who looked so nice then!' When she was a child of three or four she had for some time slept in the same room as her father and everything goes to suggest that she used then to throw back her clothes in her sleep to please her father. The subsequent repression of her pleasure in exhibiting herself was the motive for her secretiveness in the treatment, her dislike of showing herself openly.

And here is another scene from the same dream. She was reading her own case history, which she had before her in print. In it was a statement that 'a young man murdered his *fiancée* - cocoa - that comes under anal erotism.' This last phrase was a thought that she had in the dream at the mention of cocoa. - The interpretation of this piece of the dream was even more difficult than the former one. It emerged at last that before going to sleep she had been reading my 'History of an Infantile Neurosis' (1918b), the central point of which is the real or imagined observation by a patient of his parents copulating. She had already once before related this case history to her own, and this was not the only indication that in her case as well there was a question of an observation of the same kind. The young man murdering his fiancée was a clear reference to a sadistic view of the scene of copulation. But the next element, the cocoa, was very remote from it. Her only association to cocoa was that her mother used to say that cocoa gave one a headache, and she maintained that she had heard the same thing from other women. Moreover, she had at one time identified herself with her mother by means of headaches like hers. Now I could find no link between the two elements of the dream except by supposing that she wanted to make a diversion from the consequences of the observation of coitus. No, she was saying, coitus had nothing to do with the procreation of children; children came from something one ate (as they do in fairy tales); and the mention of anal erotism, which looks like an attempt in the dream at interpretation, supplemented the infantile theory which she had called to her help, by adding anal birth to it.

X

Astonishment is sometimes expressed at the fact that the dreamer's ego can appear two or more times in the manifest dream, once as himself and again disguised behind the figures of other people. During the course of the construction of the dream, the secondary revision has evidently sought to obliterate this multiplicity of the ego, which cannot fit in with any possible scenic situation; but it is re-established by the work of interpretation. In itself this multiplicity is no more remarkable than the multiple appearance of the ego in a waking thought, especially when the ego divides itself into subject and object, puts one part of itself as an observing and critical agency in contrast to the other, or compares its present nature with its recollected past, which was also ego once; for instance, in such sentences as 'When I think what I've done to this man' or 'When I think that I too was a child once'. But I should reject as a meaningless and unjustifiable piece of speculation the notion that *all* figures that appear in a dream are to be regarded as fragmentations and representatives of the dreamer's own ego. It is enough that we should keep firmly to the fact that the separation of the ego from an observing, critical, punishing agency (an ego ideal) must be taken into account in the interpretation of dreams as well.

SOME ADDITIONAL NOTES ON DREAM-INTERPRETATION AS A WHOLE
(1925)

Intentionally left blank

SOME ADDITIONAL NOTES ON DREAM-INTERPRETATION AS A WHOLE

(A) THE LIMITS TO THE POSSIBILITY OF INTERPRETATION

It may be asked whether it is possible to give a complete and assured translation into the language of waking life (that is, an interpretation) of every product of dream-life. This question will not be treated here in the abstract but with reference to the conditions under which one works at interpreting dreams.

Our mental activities pursue either a useful aim or an immediate yield of pleasure. In the former case what we are dealing with are intellectual judgements, preparations for action or the conveyance of information to other people. In the latter case we describe these activities as play or phantasy. What is useful is itself (as is well known) only a circuitous path to pleasurable satisfaction. Now, dreaming is an activity of the second kind, which is indeed, from the point of view of evolution, the earlier one. It is misleading to say that dreams are concerned with the tasks of life before us or seek to find a solution for the problems of our daily work. That is the business of preconscious thought. Useful work of this kind is as remote from dreams as is any intention of conveying information to another person. When a dream deals with a problem of actual life, it solves it in the manner of an irrational wish and not in the manner of a reasonable reflection. There is only one useful task, only one function, that can be ascribed to a dream, and that is the guarding of sleep from interruption. A dream may be described as a piece of phantasy working on behalf of the maintenance of sleep.

It follows from this that it is on the whole a matter of indifference to the sleeping ego what may be dreamt during the night so long as the dream performs its task, and that those dreams best fulfil their function about which one knows nothing after waking. If it so often happens otherwise, if we remember dreams - even after years and decades - it always means that there has been an irruption of the repressed unconscious into the normal ego. Without this concession to it the repressed would not have consented to lend its help to the removal of the threat of disturbance to sleep. We know that it is the fact of this irruption that gives dreams their importance for psychopathology. If we can uncover a dream's motivating force, we shall obtain unsuspected information about the repressed impulses in the unconscious; and on the other hand, if we can undo its distortions, we shall overhear preconscious thought taking place in states of internal reflection which would not have attracted consciousness to themselves during the day-time.

No one can practise the interpretation of dreams as an isolated activity: it remains a part of the work of analysis. In analysis we direct our interest according to necessity, now to the preconscious content of the dream and now to the unconscious contribution to its formation; and we often neglect the one element in favour of the other. Nor would it be of any avail for anyone to endeavour to interpret dreams outside analysis. He would not succeed in escaping the conditions of the analytic situation; and if he worked at his own dreams, he would be undertaking a self-analysis. This comment would not apply to someone who did without the dreamer's collaboration and sought to interpret dreams by intuitive insight. But dream-interpretation of such a kind, without reference to the dreamer's associations, would in the most favourable case remain a piece of unscientific virtuosity of very doubtful value.

If one practises dream-interpretation according to the sole justifiable technical procedure, one soon notices that success depends entirely upon the tension of resistance between the awakened ego and the repressed unconscious. Work under a 'high pressure of resistance' demands (as I have explained elsewhere) a different attitude on the part of the analyst from work under a low pressure. In analysis one has for long periods at a time to deal with strong resistances which are still unknown to one and which it will in any case be impossible to overcome so long as they remain unknown. It is therefore not to be wondered at that only a certain portion of a patient's dream-products can be translated and made use of, and, even at that, most often incompletely. Even if, owing to one's own experience, one is in a position to understand many dreams to the interpretation of which the dreamer has contributed little, one must always remember that the certainty of such interpretations remains in doubt and one hesitates to press one's conjectures upon the patient.

Critical voices will now be raised. It will be objected that, since it is not possible to interpret every dream that is dealt with, one should cease asserting more than one can establish and should be content to say that *some* dreams can be shown by interpretation to have a meaning but that as to the rest we are in ignorance. But the very fact that success in interpretation depends upon the resistance absolves the analyst from the necessity for such modesty. He may have the experience of a dream that was at first unintelligible becoming clear during the very same hour after some fortunate remark has got rid of one of the dreamer's resistances. A portion of the dream which the patient had hitherto forgotten may suddenly occur to him and may bring the key to the interpretation; or a new association may emerge which may throw light upon the darkness. It sometimes happens, too, that, after months or years of analytic labour, one returns to a dream which at the beginning of the treatment seemed meaningless and incomprehensible but which is now, in the light of knowledge obtained in the meantime, completely elucidated. And if one further takes into consideration the argument from the theory of dreams that the model dream-products of children invariably have a clear meaning and are easy to interpret, then it will be justifiable to assert that dreams are quite generally mental structures that are capable of interpretation, though the situation may not always allow of an interpretation being reached.

When the interpretation of a dream has been discovered, it is not always easy to decide whether it is a 'complete' one - that is, whether further preconscious thoughts may not also have found expression in the same dream. In that case we must consider the meaning proved which is based on the dreamer's associations and our estimate of the situation, without on that account feeling bound to reject the other meaning. It remains possible, though unproven; one must become accustomed to a dream being thus capable of having many meanings. Moreover, the blame for this is not always to be laid upon incompleteness of the work of interpretation; it may just as well be inherent in the latent dream-thoughts themselves. Indeed it may happen in waking life, quite apart from the situation of dream-interpretation, that one is uncertain whether some remark that one has heard or some piece of information that one has received is open to construction this way or that, or whether it is hinting at something else beyond its obvious meaning.

One interesting occurrence which has been insufficiently investigated is to be seen where the same manifest dream-content gives simultaneous expression to a set of concrete ideas and to an abstract line of thought based upon them. It is of course difficult for the dream-work to find a means for representing abstract thoughts.

(B) MORAL RESPONSIBILITY FOR THE CONTENT OF DREAMS

In the introductory chapter of this book (which discusses 'The Scientific Literature Dealing with the Problem of Dreams') I have shown the way in which writers have reacted to what is felt as the distressing fact that the unbridled content of dreams is so often at odds with the moral sense of the dreamer. (I deliberately avoid speaking of 'criminal' dreams, as such a description, which would overstep the limits of psychological interest, seems to me quite uncalled-for.) The immoral character of dreams has naturally provided a fresh motive for denying them any psychical value: if dreams are the meaningless product of disordered mental activity, then there can be no ground for assuming responsibility for their apparent content.

The problem of responsibility for the manifest content of dreams has been fundamentally shifted and indeed disposed of by the explanations given in my *Interpretation of Dreams*.

We know now that the manifest content is a deception, a *façade*. It is not worth while to submit it to an ethical examination or to take its breaches of morality any more seriously than its breaches of logic or mathematics. When the 'content' of the dream is spoken of, what must be referred to can only be the content of the preconscious thoughts and of the repressed wishful impulse which are revealed behind the *façade* of the dream by the work of interpretation. Nevertheless, this immoral *façade* has a question to put to us. We have heard that the latent dream-thoughts have to submit to a severe censorship before they are allowed access to the manifest content. How can it happen, then, that this censorship, which makes difficulties over more trivial things, breaks down so completely over these manifestly immoral dreams?

The answer is not easy to come by and may perhaps not seem completely satisfying. If, in the first place, one submits these dreams to interpretation, one finds that some of them have given no offence to the censorship because *au fond* they have no bad meaning. They are innocent boastings or identifications that put up a mask of pretence; they have not been censored because they do not tell the truth. But others of them - and, it must be admitted, the majority - really mean what they say and have undergone no distortion from the censorship. They are an expression of immoral, incestuous and perverse impulses or of murderous and sadistic lusts. The dreamer reacts to many of these dreams by waking up in a fright, in which case the situation is no longer obscure to us. The censorship has neglected its task, this has been noticed too late, and the generation of anxiety is a substitute for the distortion that has been omitted. In still other instances of such dreams, even that expression of affect is absent. The objectionable matter is carried along by the height of the sexual excitement that has been reached during sleep, or it is viewed with the same tolerance with which even a waking person can regard a fit of rage, an angry mood or the indulgence in cruel phantasies.

But our interest in the genesis of these *manifestly* immoral dreams is greatly reduced when we find from analysis that the majority of dreams - innocent dreams, dreams without affect and anxiety-dreams - are revealed, when the distortions of the censorship have been undone, as the fulfilments of immoral - egoistic, sadistic, perverse or incestuous - wishful impulses. As in the world of waking life, these masked criminals are far commoner than those with their vizors raised. The straightforward dream of sexual relations with one's mother, which Jocasta alludes to in the *Oedipus Rex*, is a rarity in comparison with all the multiplicity of dreams which psycho-analysis must interpret in the same sense.

I have dealt so exhaustively in these pages with this characteristic of dreams, which indeed provides the motive for their distortion, that I can pass at once from this topic to the problem that lies before us: Must one assume responsibility for the content of one's dreams? For the sake of completeness, it should, however, be added that dreams do not always offer immoral wish-fulfilments, but often energetic reactions against them in the form of 'punishment dreams'. In other words, the dream-censorship cannot only express itself in distortions and the generation of anxiety, but can go so far as to blot out the immoral subject-matter completely and replace it by something else that serves as an atonement, though it allows one to see what lies behind. But the problem of responsibility for the immoral content of dreams no longer exists for us as it formerly did for writers who knew nothing of latent dream-thoughts and the repressed part of our mental life. Obviously one must hold oneself responsible for the evil impulses of one's dreams. What else is one to do with them? Unless the content of the dream (rightly understood) is inspired by alien spirits, it is a part of my own being. If I seek to classify the impulses that are present in me according to social standards into good and bad, I must assume responsibility for both sorts; and if, in defence, I say that what is unknown, unconscious and repressed in me is not my 'ego', then I shall not be basing my position upon psycho-analysis, I shall not have accepted its conclusions - and I shall perhaps be taught better by the criticisms of my fellow-men, by the disturbances in my actions and the confusion of my feelings. I shall perhaps learn that what I am disavowing not only 'is' in me but sometimes 'acts' from out of me as well.

It is true that in the metapsychological sense this bad repressed content does not belong to my 'ego' - that is, assuming that I am a morally blameless individual - but to an 'id' upon which my ego is seated. But this ego developed out of the id, it forms with it a single biological unit, it is only a specially modified peripheral portion of it, and it is subject to the influences and obeys the suggestions that arise from the id. For any vital purpose, a separation of the ego from the id would be a hopeless undertaking.

Moreover, if I were to give way to my moral pride and tried to decree that for purposes of moral valuation I might disregard the evil in the id and need not make my ego responsible for it, what use would that be to me? Experience shows me that I nevertheless *do* take that responsibility, that I am somehow compelled to do so. Psycho-analysis has made us familiar with a pathological condition, obsessional neurosis, in which the poor ego feels itself responsible for all sorts of evil impulses of which it knows nothing, impulses which are brought up against it in consciousness but which it is unable to acknowledge. Something of this is present in every normal person. It is a remarkable fact that the more moral he is the more sensitive is his 'conscience'. It is just as though we could say that the healthier a man is, the more liable he is to contagions and to the effects of injuries. This is no doubt because conscience is itself a reaction-formation against the evil that is perceived in the id. The more strongly the latter is suppressed, the more active is the conscience.

The ethical narcissism of humanity should rest content with the knowledge that the fact of distortion in dreams, as well as the existence of anxiety-dreams and punishment-dreams, afford just as clear evidence of his *moral* nature as dream-interpretation gives of the existence and strength of his *evil* nature. If anyone is dissatisfied with this and would like to be 'better' than he was created, let him see whether he can attain anything more in life than hypocrisy or inhibition.

The physician will leave it to the jurist to construct for social purposes a responsibility that is artificially limited to the metapsychological ego. It is notorious that the greatest difficulties are encountered by the attempts to derive from such a construction practical consequences which are not in contradiction to human feelings.

(C) THE OCCULT SIGNIFICANCE OF DREAMS

There seems to be no end to the problems of dream-life. But this can only be surprising if we forget that all the problems of mental life recur in dreams with the addition of a few new ones arising from the special nature of dreams. Many of the things that we study in dreams, because we meet with them there, have nevertheless little or nothing to do with the psychological peculiarity of dreams. Thus, for instance, symbolism is not a dream-problem, but a topic connected with our archaic thinking - our 'basic language', as it was aptly called by the paranoic Schreber. It dominates myths and religious ritual no less than dreams, and dream-symbolism can scarcely even claim that it is peculiar in that it conceals more particularly things that are important sexually. Again, it is not to be expected that the explanation of anxiety-dreams will be found in the theory of dreams. Anxiety is a problem rather of neurosis, and all that remains to be discussed is how it comes about that anxiety can arise under dream-conditions.

The position is just the same, I think, in the matter of the relation of dreams to the alleged facts of the occult world. But, since dreams themselves have always been mysterious things, they have been brought into intimate connection with the other unknown mysteries. No doubt, too, they have a historic claim to that position, since in primaeval ages, when our mythology was being formed, dream-images may have played a part in the origin of ideas about spirits.

There would seem to be two categories of dreams with a claim to being reckoned as occult phenomena: prophetic dreams and telepathic ones. A countless multitude of witnesses speak in favour of both of them, while against both of them there is the obstinate aversion, or maybe prejudice, of science.

There can, indeed, be no doubt that there are such things as prophetic dreams, in the sense that their content gives some sort of picture of the future; the only question is whether these predictions coincide to any noticeable extent with what really happens subsequently. I must confess that upon this point my resolution in favour of impartiality deserts me. The notion that there is any mental power, apart from acute calculation, which can foresee future events in detail is on the one hand too much in contradiction to all the expectations and presumptions of science and on the other hand corresponds too closely to certain ancient and familiar human desires which criticism must reject as unjustifiable pretensions. I am therefore of opinion that after one has taken into account the untrustworthiness, credulity and unconvincingness of most of these reports, together with the possibility of falsifications of memory facilitated by emotional causes and the inevitability of a few lucky shots, it may be anticipated that the spectre of veridical prophetic dreams will disappear into nothing. Personally, I have never experienced anything or learnt of anything that could encourage a more favourable presumption.

It is otherwise with telepathic dreams. But at this point it must be made quite clear that no one has yet maintained that telepathic phenomena - the reception of a mental process by one person from another by means other than sensory perception - are exclusively related to dreams. Thus once again telepathy is not a dream-problem: our judgement upon whether it exists or not need not be based on a study of telepathic dreams.

If reports of telepathic occurrences (or, to speak less exactly, of thought-transference) are submitted to the same criticism as stories of other occult events, there remains a considerable amount of material which cannot be so easily neglected. Further, it is much more possible to collect observations and experiences of one's own in this field which justify a favourable attitude to the problem of telepathy, even though they may not be enough to carry an assured conviction. One arrives at a provisional opinion that it may well be that telepathy really exists and that it provides the kernel of truth in many other hypotheses that would otherwise be incredible.

It is certainly right in what concerns telepathy to adhere obstinately to the same sceptical position and only to yield grudgingly to the force of evidence. I believe I have found a class of material which is exempt from the doubts which are otherwise justified - namely, unfulfilled prophecies made by professional fortune-tellers. Unluckily, I have but few such observations at my disposal; but two among these have made a powerful impression on me. I am not in a position to describe them in such detail as would produce a similar effect upon other people, and I must restrict myself to bringing out a few essential points.

A prediction had been made, then, to the enquirers (at a strange place and by a strange fortune-teller, who was at the same time carrying out some, presumably irrelevant, ritual) that something would happen to them at a particular time, which in fact did *not* come true. The date at which the prophecy should have been fulfilled was long past. It was striking that those concerned reported their experience not with derision or disappointment but with obvious satisfaction. Included among what had been told them there were certain quite definite details which seemed capricious and unintelligible and would only have been justified if they had hit the mark. Thus, for instance, the palmist told a woman who was twenty-seven (though she looked much younger) and who had taken off her wedding-ring, that she would be married and have two children before she was thirty-two. The woman was forty-three when, now seriously ill, she told me the story in her analysis: she had remained childless. If one knew her private history (of which the 'Professor' in the lounge of the Paris hotel was certainly ignorant) one could understand the two numbers included in the prophecy. The girl had married after an unusually intense attachment to her father and had then had a passionate longing for children, so as to be able to put her husband in the place of her father. After years of disappointment, when she was on the brink of a neurosis, she obtained the prophecy, which promised her - the lot of her mother. For it was a fact that the latter had had two children by the time she was thirty-two. Thus it was only by the help of psycho-analysis that it was possible to give a significant interpretation of the peculiarities of this pretended message from without. But there was then no better explanation of the whole, unequivocally determined chain of events than to suppose that a strong wish on the part of the questioner - the strongest unconscious wish, in fact, of her whole emotional life and the motive force of her impending neurosis - had made itself manifest to the fortune-teller by being directly transferred to him while his attention was being distracted by the performances he was going through.

I have often had an impression, in the course of experiments in my private circle, that strongly emotionally coloured recollections can be successfully transferred without much difficulty. If one has the courage to subject to an analytic examination the associations of the person to whom the thoughts are supposed to be transferred, correspondences often come to light which would otherwise have remained undiscovered. On the basis of a number of experiences I am inclined to draw the conclusion that thought-transference of this kind comes about particularly easily at the moment at which an idea emerges from the unconscious, or, in theoretical terms, as it passes over from the 'primary process' to the 'secondary process'.

In spite of the caution which is prescribed by the importance, novelty and obscurity of the subject, I feel that I should not be justified in holding back any longer these considerations upon the problem of telepathy. All of this has only this much to do with dreams: if there are such things as telepathic messages, the possibility cannot be dismissed of their reaching someone during sleep and coming to his knowledge in a dream. Indeed, on the analogy of other perceptual and intellectual material, the further possibility arises that telepathic messages received in the course of the day may only be dealt with during a dream of the following night. There would then be nothing contradictory in the material that has been telepathically communicated being modified and transformed in the dream like any other material. It would be satisfactory if with the help of psycho-analysis we could obtain further and better authenticated knowledge of telepathy.

THE INFANTILE GENITAL ORGANIZATION
(AN INTERPOLATION INTO THE THEORY OF SEXUALITY)
(1923)

Intentionally left blank

THE INFANTILE GENITAL ORGANIZATION (AN INTERPOLATION INTO THE THEORY OF SEXUALITY)

The difficulty of the work of research in psycho-analysis is clearly shown by the fact of its being possible, in spite of whole decades of unremitting observation, to overlook features that are of general occurrence and situations that are characteristic, until at last they confront one in an unmistakable form. The remarks that follow are intended to make good a neglect of this sort in the field of infantile sexual development.

Readers of my *Three Essays on the Theory of Sexuality* (1905*d*) will be aware that I have never undertaken any thorough remodelling of that work in its later editions, but have retained the original arrangement and have kept abreast of the advances made in our knowledge by means of interpolations and alterations in the text. In doing this, it may often have happened that what was old and what was more recent did not admit of being merged into an entirely uncontradictory whole. Originally, as we know, the accent was on a portrayal of the fundamental difference between the sexual life of children and of adults; later, the *pregenital organizations* of the libido made their way into the foreground, and also the remarkable and momentous fact of the *diphasic onset* of sexual development. Finally, our interest was engaged by the *sexual researches* of children; and from this we were able to recognize the far-reaching *approximation of the final outcome of sexuality in childhood* (in about the fifth year) to the definitive form taken by it in the adult. This is the point at which I left things in the last (1922) edition of my *Three Essays*.

In that volume (p. 1400) I wrote that 'the choice of an object, such as we have shown to be characteristic of the pubertal phase of development, has already frequently or habitually been effected during the years of childhood: that is to say, the whole of the sexual currents have become directed towards a single person in relation to whom they seek to achieve their aims. This then is the closest approximation possible in childhood to the final form taken by sexual life after puberty. The only difference lies in the fact that in childhood the combination of the component instincts and their subordination under the primacy of the genitals have been effected only very incompletely or not at all. Thus the establishment of that primacy in the service of reproduction is the last phase through which the organization of sexuality passes.'

To-day I should no longer be satisfied with the statement that in the early period of childhood the primacy of the genitals has been effected only very incompletely or not at all. The approximation of the child's sexual life to that of the adult goes much further and is not limited solely to the coming into being of the choice of an object. Even if a proper combination of the component instincts under the primacy of the genitals is not effected, nevertheless, at the height of the course of development of infantile sexuality, interest in the genitals and in their activity acquires a dominating significance which falls little short of that reached in maturity. At the same time, the main characteristic of this 'infantile genital organization' is its *difference* from the final genital organization of the adult. This consists in the fact that, for both sexes, only one genital, namely the male one, comes into account. What is present, therefore, is not a primacy of the genitals, but a primacy of the *phallus*.

Unfortunately we can describe this state of things only as it affects the male child; the corresponding processes in the little girl are not known to us. The small boy undoubtedly perceives the distinction between men and women, but to begin with he has no occasion to connect it with a difference in their genitals. It is natural for him to assume that all other living beings, humans and animals, possess a genital like his own; indeed, we know that he looks for an organ analogous to his own in inanimate things as well.¹ This part of the body, which is easily excitable, prone to changes and so rich in sensations, occupies the boy's interest to a high degree and is constantly setting new tasks to his instinct for research. He wants to see it in other people as well, so as to compare it with his own; and he behaves as though he had a vague idea that this organ could and should be bigger. The driving force which this male portion of the body will develop later at puberty expresses itself at this period of life mainly as an urge to investigate, as sexual curiosity. Many of the acts of exhibitionism and aggression which children commit, and which in later years would be judged without hesitation to be expressions of lust, prove in analysis to be experiments undertaken in the service of sexual research.

¹ It is, incidentally, remarkable what a small degree of attention the other part of the male genitals, the little sac with its contents, attracts in children. From all one hears in analyses, one would not guess that the male genitals consisted of anything more than the penis.

In the course of these researches the child arrives at the discovery that the penis is not a possession which is common to all creatures that are like himself. An accidental sight of the genitals of a little sister or playmate provides the occasion for this discovery. In unusually intelligent children, the observation of girls urinating will even earlier have aroused a suspicion that there is something different here. For they will have seen a different posture and heard a different sound, and will have made attempts to repeat their observations so as to obtain enlightenment. We know how children react to their first impressions of the absence of a penis. They disavow the fact and believe that they *do* see a penis, all the same. They gloss over the contradiction between observation and preconception by telling themselves that the penis is still small and will grow bigger presently; and they then slowly come to the emotionally significant conclusion that after all the penis had at least been there before and been taken away afterwards. The lack of a penis is regarded as a result of castration, and so now the child is faced with the task of coming to terms with castration in relation to himself. The further developments are too well known generally to make it necessary to recapitulate them here. But it seems to me that *the significance of the castration complex can only be rightly appreciated if its origin in the phase of phallic primacy is also taken into account.*¹

¹ It has been quite correctly pointed out that a child gets the idea of a narcissistic injury through a bodily loss from the experience of losing his mother's breast after sucking, from the daily surrender of his faeces and, indeed, even from his separation from the womb at birth. Nevertheless, one ought not to speak of a castration complex until this idea of a loss has become connected with the male genitals.

We know, too, to what a degree depreciation of women, horror of women, and a disposition to homosexuality are derived from the final conviction that women have no penis. Ferenczi (1923) has recently, with complete justice, traced back the mythological symbol of horror - Medusa's head - to the impression of the female genitals devoid of a penis.¹

It should not be supposed, however, that the child quickly and readily makes a generalization from his observation that some women have no penis. He is in any case debarred from doing so by his assumption that the lack of a penis is the result of having been castrated as a punishment. On the contrary, the child believes that it is only unworthy female persons that have lost their genitals - females who, in all probability, were guilty of inadmissible impulses similar to his own. Women whom he respects, like his mother, retain a penis for a long time. For him, being a woman is not yet synonymous with being without a penis.² It is not till later, when the child takes up the problems of the origin and birth of babies, and when he guesses that only women can give birth to them - it is only then that the mother, too, loses her penis. And, along with this, quite complicated theories are built up to explain the exchange of the penis for a baby. In all this, the female genitals never seem to be discovered. The baby, we know, is supposed to live inside the mother's body (in her bowel) and to be born through the intestinal outlet. These last theories carry us beyond the stretch of time covered by the infantile sexual period.

¹ I should like to add that what is indicated in the myth is the *mother's* genitals. Athene, who carries Medusa's head on her armour, becomes in consequence the unapproachable woman, the sight of whom extinguishes all thought of a sexual approach.

² I learnt from the analysis of a young married woman who had no father but several aunts that she clung, until quite far on in the latency period, to the belief that her mother and her aunts had a penis. One of her aunts, however, was feeble-minded; and she regarded this aunt as castrated, as she felt herself to be.

It is not unimportant to bear in mind what transformations are undergone, during the sexual development of childhood, by the polarity of sex with which we are familiar. A first antithesis is introduced with the choice of object, which, of course, presupposes a subject and an object. At the stage of the pregenital sadistic-anal organization, there is as yet no question of male and female; the antithesis between *active* and *passive* is the dominant one.¹ At the following stage of infantile genital organization, which we now know about, *maleness* exists, but not femaleness. The antithesis here is between having *a male genital* and being *castrated*. It is not until development has reached its completion at puberty that the sexual polarity coincides with *male* and *female*. Maleness combines subject, activity and possession of the penis; femaleness takes over object and passivity. The vagina is now valued as a place of shelter for the penis; it enters into the heritage of the womb.

NEUROSIS AND PSYCHOSIS
(1924)

Intentionally left blank

4064

NEUROSIS AND PSYCHOSIS

In my recently published work, *The Ego and the Id* (1923b), I have proposed a differentiation of the mental apparatus, on the basis of which a number of relationships can be represented in a simple and perspicuous manner. As regards other points - for instance, in what concerns the origin and role of the super-ego - enough remains obscure and unelucidated. Now one may reasonably expect that a hypothesis of this kind should prove useful and helpful in other directions as well, if only to enable us to see what we already know from another angle, to group it differently and to describe it more convincingly. Such an application of the hypothesis might also bring with it a profitable return from grey theory to the perpetual green of experience.

In the work I have mentioned I described the numerous dependent relationships of the ego, its intermediate position between the external world and the id and its efforts to humour all its masters at once. In connection with a train of thought raised in other quarters, which was concerned with the origin and prevention of the psychoses, a simple formula has now occurred to me which deals with what is perhaps the most important genetic difference between a neurosis and a psychosis: *neurosis is the result of a conflict between the ego and its id, whereas psychosis is the analogous outcome of a similar disturbance in the relations between the ego and the external world.*

There are certainly good grounds for being suspicious of such simple solutions of a problem. Moreover, the most that we may expect is that this formula will turn out to be correct in the roughest outline. But even that would be something. One recalls at once, too, a whole number of discoveries and findings which seem to support our thesis. All our analyses go to show that the transference neuroses originate from the ego's refusing to accept a powerful instinctual impulse in the id or to help it to find a motor outlet, or from the ego's forbidding that impulse the object at which it is aiming. In such a case the ego defends itself against the instinctual impulse by the mechanism of repression. The repressed material struggles against this fate. It creates for itself, along paths over which the ego has no power, a substitutive representation (which forces itself upon the ego by way of a compromise) - the symptom. The ego finds its unity threatened and impaired by this intruder, and it continues to struggle against the symptom, just as it fended off the original instinctual impulse. All this produces the picture of a neurosis. It is no contradiction to this that, in undertaking the repression, the ego is at bottom following the commands of its super-ego - commands which, in their turn, originate from influences in the external world that have found representation in the super-ego. The fact remains that the ego *has* taken sides with those powers, that in it their demands have more strength than the instinctual demands of the id, and that the ego is the power which sets the repression in motion against the portion of the id concerned and which fortifies the repression by means of the anticathexis of resistance. The ego has come into conflict with the id in the service of the super-ego and of reality; and this is the state of affairs in every transference neurosis.

On the other side, it is equally easy, from the knowledge we have so far gained of the mechanism of the psychoses, to adduce examples which point to a disturbance in the relationship between the ego and the external world. In Meynert's *amentia* - an acute hallucinatory confusion which is perhaps the most extreme and striking form of psychosis - either the external world is not perceived at all, or the perception of it has no effect whatever. Normally, the external world governs the ego in two ways: firstly, by current, present perceptions which are always renewable, and secondly, by the store of memories of earlier perceptions which, in the shape of an 'internal world', form a possession of the ego and a constituent part of it. In *amentia*, not only is the acceptance of new perceptions refused, but the internal world, too, which, as a copy of the external world, has up till now represented it, loses its significance (its cathexis) - The ego creates, autocratically, a new external and internal world; and there can be no doubt of two facts - that this new world is constructed in accordance with the id's wishful impulses, and that the motive of this dissociation from the external world is some very serious frustration by reality of a wish - a frustration which seems intolerable. The close affinity of this psychosis to normal dreams is unmistakable. A precondition of dreaming, moreover, is a state of sleep, and one of the features of sleep is a complete turning away from perception and the external world.

We know that other forms of psychosis, the schizophrenias, are inclined to end in affective hebetude - that is, in a loss of all participation in the external world. In regard to the genesis of delusions, a fair number of analyses have taught us that the delusion is found applied like a patch over the place where originally a rent had appeared in the ego's relation to the external world. If this precondition of a conflict with the external world is not much more noticeable to us than it now is, that is because, in the clinical picture of the psychosis, the manifestations of the pathogenic process are often overlaid by manifestations of an attempt at a cure or a reconstruction.

The aetiology common to the onset of a psychoneurosis and of a psychosis always remains the same. It consists in a frustration, a non-fulfilment of one of those childhood wishes which are for ever undefeated and which are so deeply rooted in our phylogenetically determined organization. This frustration is in the last resort always an external one; but in the individual case it may proceed from the internal agency (in the super-ego) which has taken over the representation of the demands of reality. The pathogenic effect depends on whether, in a conflictual tension of this kind, the ego remains true to its dependence on the external world and attempts to silence the id, or whether it lets itself be overcome by the id and thus torn away from reality. A complication is introduced into this apparently simple situation, however, by the existence of the super-ego, which, through a link that is not yet clear to us, unites in itself influences coming from the id as well as from the external world, and is to some extent an ideal model of what the whole endeavour of the ego is aiming at - a reconciliation between its various dependent relationships. The attitude of the super-ego should be taken into account - which has not hitherto been done - in every form of psychical illness. We may provisionally assume that there must also be illnesses which are based on a conflict between the ego and the super-ego. Analysis gives us a right to suppose that melancholia is a typical example of this group; and we would set aside the name of 'narcissistic psychoneuroses' for disorders of that kind. Nor will it clash with our impressions if we find reasons for separating states like melancholia from the other psychoses. We now see that we have been able to make our simple genetic formula more complete, without dropping it. Transference neuroses correspond to a conflict between the ego and the id; narcissistic neuroses, to a conflict between the ego and the super-ego; and psychoses, to one between the ego and the external world. It is true that we cannot tell at once whether we have really gained any new knowledge by this, or have only enriched our store of formulas; but I think that this possible application of the proposed differentiation of the mental apparatus into an ego, a super-ego and an id cannot fail to give us courage to keep that hypothesis steadily in view.

The thesis that neuroses and psychoses originate in the ego's conflicts with its various ruling agencies - that is, therefore, that they reflect a failure in the functioning of the ego, which is at pains to reconcile all the various demands made on it - this thesis needs to be supplemented in one further point. One would like to know in what circumstances and by what means the ego can succeed in emerging from such conflicts, which are certainly always present, without falling ill. This is a new field of research, in which no doubt the most varied factors will come up for examination. Two of them, however, can be stressed at once. In the first place, the outcome of all such situations will undoubtedly depend on economic considerations - on the relative magnitudes of the trends which are struggling with one another. In the second place, it will be possible for the ego to avoid a rupture in any direction by deforming itself, by submitting to encroachments on its own unity and even perhaps by effecting a cleavage or division of itself. In this way the inconsistencies, eccentricities and follies of men would appear in a similar light to their sexual perversions, though the acceptance of which they spare themselves repressions.

In conclusion, there remains to be considered the question of what the mechanism, analogous to repression, can be by means of which the ego detaches itself from the external world. This cannot, I think, be answered without fresh investigations; but such a mechanism, it would seem, must, like repression, comprise a withdrawal of the cathexis sent out by the ego.

THE ECONOMIC PROBLEM OF MASOCHISM
(1924)

Intentionally left blank

4070

THE ECONOMIC PROBLEM OF MASOCHISM

The existence of a masochistic trend in the instinctual life of human beings may justly be described as mysterious from the economic point of view. For if mental processes are governed by the pleasure principle in such a way that their first aim is the avoidance of unpleasure and the obtaining of pleasure, masochism is incomprehensible. If pain and unpleasure can be not simply warnings but actually aims, the pleasure principle is paralysed - it is as though the watchman over our mental life were put out of action by a drug.

Thus masochism appears to us in the light of a great danger, which is in no way true of its counterpart, sadism. We are tempted to call the pleasure principle the watchman over our life rather than merely over our mental life. But in that case we are faced with the task of investigating the relationship of the pleasure principle to the two classes of instincts which we have distinguished - the death instincts and the erotic (libidinal) life instincts; and we cannot proceed further in our consideration of the problem of masochism till we have accomplished that task.

It will be remembered that we have taken the view that the principle which governs all mental processes is a special case of Fechner's 'tendency towards stability',¹ and have accordingly attributed to the mental apparatus the purpose of reducing to nothing, or at least of keeping as low as possible, the sums of excitation which flow in upon it. Barbara Low has suggested the name of 'Nirvana principle' for this supposed tendency, and we have accepted the term. But we have unhesitatingly identified the pleasure-unpleasure principle with this Nirvana principle. Every unpleasure ought thus to coincide with a heightening, and every pleasure with a lowering, of mental tension due to stimulus; the Nirvana principle (and the pleasure principle which is supposedly identical with it) would be entirely in the service of the death instincts, whose aim is to conduct the restlessness of life into the stability of the inorganic state, and it would have the function of giving warnings against the demands of the life instincts - the libido - which try to disturb the intended course of life. But such a view cannot be correct. It seems that in the series of feelings of tension we have a direct sense of the increase and decrease of amounts of stimulus, and it cannot be doubted that there are pleasurable tensions and unpleasurable relaxations of tension. The state of sexual excitation is the most striking example of a pleasurable increase of stimulus of this sort, but it is certainly not the only one.

¹ *Beyond the Pleasure Principle* (1920g).

Pleasure and unpleasure, therefore, cannot be referred to an increase or decrease of a quantity (which we describe as 'tension due to stimulus'), although they obviously have a great deal to do with that factor. It appears that they depend, not on this quantitative factor, but on some characteristic of it which we can only describe as a qualitative one. If we were able to say what this qualitative characteristic is, we should be much further advanced in psychology. Perhaps it is the rhythm, the temporal sequence of changes, rises and falls in the quantity of stimulus. We do not know.

However this may be, we must perceive that the Nirvana principle, belonging as it does to the death instinct, has undergone a modification in living organisms through which it has become the pleasure principle; and we shall henceforward avoid regarding the two principles as one. It is not difficult, if we care to follow up this line of thought, to guess what power was the source of the modification. It can only be the life instinct, the libido, which has thus, alongside of the death instinct, seized upon a share in the regulation of the processes of life. In this way we obtain a small but interesting set of connections. The *Nirvana* principle expresses the trend of the death instinct; the *pleasure* principle represents the demands of the libido; and the modification of the latter principle, the *reality* principle, represents the influence of the external world.

None of these three principles is actually put out of action by another. As a rule they are able to tolerate one another, although conflicts are bound to arise occasionally from the fact of the differing aims that are set for each - in one case a quantitative reduction of the load of the stimulus, in another a qualitative characteristic of the stimulus, and, lastly, a postponement of the discharge of the stimulus and a temporary acquiescence in the unpleasure due to tension.

The conclusion to be drawn from these considerations is that the description of the pleasure principle as the watchman over our life cannot be rejected.

To return to masochism. Masochism comes under our observation in three forms: as a condition imposed on sexual excitation, as an expression of the feminine nature, and as a norm of behaviour. We may, accordingly, distinguish an *erotogenic*, a *feminine* and a *moral* masochism. The first, the erotogenic, masochism - pleasure in pain - lies at the bottom of the other two forms as well. Its basis must be sought along biological and constitutional lines and it remains incomprehensible unless one decides to make certain assumptions about matters that are extremely obscure. The third, and in some respects the most important, form assumed by masochism has only recently been recognized by psycho-analysis as a sense of guilt which is mostly unconscious; but it can already be completely explained and fitted into the rest of our knowledge. Feminine masochism, on the other hand, is the one that is most accessible to our observation and least problematical, and it can be surveyed in all its relations. We will begin our discussion with it.

We have sufficient acquaintance with this kind of masochism in men (to whom, owing to the material at my command, I shall restrict my remarks), derived from masochistic - and therefore often impotent - subjects whose phantasies either terminate in an act of masturbation or represent a sexual satisfaction in themselves. The real-life performances of masochistic perverts tally completely with these phantasies, whether the performances are carried out as an end in themselves or serve to induce potency and to lead to the sexual act. In both cases - for the performances are, after all, only a carrying-out of the phantasies in play - the manifest content is of being gagged, bound, painfully beaten, whipped, in some way maltreated, forced into unconditional obedience, dirtied and debased. It is far more rare for mutilations to be included in the content, and then only subject to strict limitations. The obvious interpretation, and one easily arrived at, is that the masochist wants to be treated like a small and helpless child, but, particularly, like a naughty child. It is unnecessary to quote cases to illustrate this; for the material is very uniform and is accessible to any observer, even to non-analysts. But if one has an opportunity of studying cases in which the masochistic phantasies have been especially richly elaborated, one quickly discovers that they place the subject in a characteristically female situation; they signify, that is, being castrated, or copulated with, or giving birth to a baby. For this reason I have called this form of masochism, *a priori* as it were, the feminine form, although so many of its features point to infantile life. This superimposed stratification of the infantile and the feminine will find a simple explanation later on. Being castrated - or being blinded, which stands for it - often leaves a negative trace of itself in phantasies, in the condition that no injury is to occur precisely to the genitals or the eyes. (Masochistic tortures, incidentally, rarely make such a serious impression as the cruelties of sadism, whether imagined or performed.) A sense of guilt, too, finds expression in the manifest content of masochistic phantasies; the subject assumes that he has committed some crime (the nature of which is left indefinite) which is to be expiated by all these painful and tormenting procedures. This looks like a superficial rationalization of the masochistic subject-matter, but behind it there lies a connection with infantile masturbation. On the other hand, this factor of guilt provides a transition to the third, moral, form of masochism.

This feminine masochism which we have been describing is entirely based on the primary, erotogenic masochism, on pleasure in pain. This cannot be explained without taking our discussion very far back.

In my *Three Essays on the Theory of Sexuality*, in the section on the sources of infantile sexuality, I put forward the proposition that 'in the case of a great number of internal processes sexual excitation arises as a concomitant effect, as soon as the intensity of those processes passes beyond certain quantitative limits'. Indeed, 'it may well be that nothing of considerable importance can occur in the organism without contributing some component to the excitation of the sexual instinct'. In accordance with this, the excitation of pain and unpleasure would be bound to have the same result, too. The occurrence of such a libidinal sympathetic excitation when there is tension due to pain and unpleasure would be an infantile physiological mechanism which ceases to operate later on. It would attain a varying degree of development in different sexual constitutions; but in any case it would provide the physiological foundation on which the psychical structure of erotogenic masochism would afterwards be erected.

The inadequacy of this explanation is seen, however, in the fact that it throws no light on the regular and close connections of masochism with its counterpart in instinctual life, sadism. If we go back a little further, to our hypothesis of the two classes of instincts which we regard as operative in the living organism, we arrive at another derivation of masochism, which, however, is not in contradiction with the former one. In (multicellular) organisms the libido meets the instinct of death, or destruction, which is dominant in them and which seeks to disintegrate the cellular organism and to conduct each separate unicellular organism into a state of inorganic stability (relative though this may be). The libido has the task of making the destroying instinct innocuous, and it fulfils the task by diverting that instinct to a great extent outwards - soon with the help of a special organic system, the muscular apparatus - towards objects in the external world. The instinct is then called the destructive instinct, the instinct for mastery, or the will to power. A portion of the instinct is placed directly in the service of the sexual function, where it has an important part to play. This is sadism proper. Another portion does not share in this transposition outwards; it remains inside the organism and, with the help of the accompanying sexual excitation described above, becomes libidinally bound there. It is in this portion that we have to recognize the original, erotogenic masochism.

We are without any physiological understanding of the ways and means by which this taming of the death instinct by the libido may be effected. So far as the psycho-analytic field of ideas is concerned, we can only assume that a very extensive fusion and amalgamation, in varying proportions, of the two classes of instincts takes place, so that we never have to deal with pure life instincts or pure death instincts but only with mixtures of them in different amounts. Corresponding to a fusion of instincts of this kind, there may, as a result of certain influences, be a *defusion* of them. How large the portions of the death instincts are which refuse to be tamed in this way by being bound to admixtures of libido we cannot at present guess.

If one is prepared to overlook a little inexactitude, it may be said that the death instinct which is operative in the organism - primal sadism - is identical with masochism. After the main portion of it has been transposed outwards on to objects, there remains inside, as a residuum of it, the erotogenic masochism proper, which on the one hand has become a component of the libido and, on the other, still has the self as its object. This masochism would thus be evidence of, and a remainder from, the phase of development in which the coalescence, which is so important for life, between the death instinct and Eros took place. We shall not be surprised to hear that in certain circumstances the sadism, or instinct of destruction, which has been directed outwards, projected, can be once more introjected, turned inwards, and in this way regress to its earlier situation. If this happens, a secondary masochism is produced, which is added to the original masochism.

Erotogetic masochism accompanies the libido through all its developmental phases and derives from them its changing psychical coatings. The fear of being eaten up by the totem animal (the father) originates from the primitive oral organization; the wish to be beaten by the father comes from the sadistic-anal phase which follows it; castration, although it is later disavowed, enters into the content of masochistic phantasies as a precipitate of the phallic stage or organization;¹ and from the final genital organization there arise, of course, the situations of being copulated with and of giving birth, which are characteristic of femaleness. The part played in masochism by the nates, too, is easily understandable, apart from its obvious basis in reality. The nates are the part of the body which is given erotogenic preference in the sadistic-anal phase, like the breast in the oral phase and the penis in the genital phase.

The third form of masochism, moral masochism, is chiefly remarkable for having loosened its connection with what we recognize as sexuality. All other masochistic sufferings carry with them the condition that they shall emanate from the loved person and shall be endured at his command. This restriction has been dropped in moral masochism. The suffering itself is what matters; whether it is decreed by someone who is loved or by someone who is indifferent is of no importance. It may even be caused by impersonal powers or by circumstances; the true masochist always turns his cheek whenever he has a chance of receiving a blow. It is very tempting, in explaining this attitude, to leave the libido out of account and to confine oneself to assuming that in this case the destructive instinct has been turned inwards again and is now raging against the self; yet there must be some meaning in the fact that linguistic usage has not given up the connection between this norm of behaviour and erotism and calls these self-injurers masochists too.

¹ See 'The Infantile Genital Organization' (1923e).

Let us keep to a habit of our technique and consider first the extreme and unmistakably pathological form of this masochism. I have described elsewhere¹ how in analytic treatment we come across patients to whom, owing to their behaviour towards its therapeutic influence, we are obliged to ascribe an 'unconscious' sense of guilt. I pointed out the sign by which such people can be recognized (a 'negative therapeutic reaction') and I did not conceal the fact that the strength of such an impulse constitutes one of the most serious resistances and the greatest danger to the success of our medical or educative aims. The satisfaction of this unconscious sense of guilt is perhaps the most powerful bastion in the subject's (usually composite) gain from illness - in the sum of forces which struggle against his recovery and refuse to surrender his state of illness. The suffering entailed by neuroses is precisely the factor that makes them valuable to the masochistic trend. It is instructive, too, to find, contrary to all theory and expectation, that a neurosis which has defied every therapeutic effort may vanish if the subject becomes involved in the misery of an unhappy marriage, or loses all his money, or develops a dangerous organic disease. In such instances one form of suffering has been replaced by another; and we see that all that mattered was that it should be possible to maintain a certain amount of suffering.

Patients do not easily believe us when we tell them about the unconscious sense of guilt. They know only too well by what torments - the pangs of conscience - a conscious sense of guilt, a consciousness of guilt, expresses itself, and they therefore cannot admit that they could harbour exactly analogous impulses in themselves without being in the least aware of them. We may, I think, to some extent meet their objection if we give up the term 'unconscious sense of guilt', which is in any case psychologically incorrect, and speak instead of a 'need for punishment', which covers the observed state of affairs just as aptly. We cannot, however, restrain ourselves from judging and localizing this unconscious sense of guilt in the same way as we do the conscious kind.

¹ *The Ego and the Id* (1923b).

We have attributed the function of conscience to the super-ego and we have recognized the consciousness of guilt as an expression of a tension between the ego and the super-ego. The ego reacts with feelings of anxiety (conscience anxiety) to the perception that it has not come up to the demands made by its ideal, the super-ego. What we want to know is how the super-ego has come to play this demanding role and why the ego, in the case of a difference with its ideal, should have to be afraid.

We have said that the function of the ego is to unite and to reconcile the claims of the three agencies which it serves; and we may add that in doing so it also possesses in the super-ego a model which it can strive to follow. For this super-ego is as much a representative of the id as of the external world. It came into being through the introjection into the ego of the first objects of the id's libidinal impulses - namely, the two parents. In this process the relation to those objects was desexualized; it was diverted from its direct sexual aims. Only in this way was it possible for the Oedipus complex to be surmounted. The super-ego retained essential features of the introjected persons - their strength, their severity, their inclination to supervise and to punish. As I have said elsewhere,¹ it is easily conceivable that, thanks to the defusion of instinct which occurs along with this introduction into the ego, the severity was increased. The super-ego - the conscience at work in the ego - may then become harsh, cruel and inexorable against the ego which is in its charge. Kant's Categorical Imperative is thus the direct heir of the Oedipus complex.

But the same figures who continue to operate in the super-ego as the agency we know as conscience after they have ceased to be objects of the libidinal impulses of the id - these same figures also belong to the real external world. It is from there that they were drawn; their power, behind which lie hidden all the influences of the past and of tradition, was one of the most strongly-felt manifestations of reality. In virtue of this concurrence, the super-ego, the substitute for the Oedipus complex, becomes a representative of the real external world as well and thus also becomes a model for the endeavours of the ego.

¹ *The Ego and the Id.*

In this way the Oedipus complex proves to be - as has already been conjectured in a historical sense¹ - the source of our individual ethical sense, our morality. The course of childhood development leads to an ever-increasing detachment from parents, and their personal significance for the super-ego recedes into the background. To the imagos they leave behind there are then linked the influences of teachers and authorities, self-chosen models and publicly recognized heroes, whose figures need no longer be introjected by an ego which has become more resistant. The last figure in the series that began with the parents is the dark power of Destiny which only the fewest of us are able to look upon as impersonal. There is little to be said against the Dutch writer Multatuli² when he replaces the *Moía* [Destiny] of the Greeks by the divine pair 'Λόγος καί' Ανάγκη, [Reason and necessity]; but all who transfer the guidance of the world to Providence, to God, or to God and Nature, arouse a suspicion that they still look upon these ultimate and remotest powers as a parental couple, in a mythological sense, and believe themselves linked to them by libidinal ties. In *The Ego and the Id* I made an attempt to derive mankind's realistic fear of death, too, from the same parental view of fate. It seems very hard to free oneself from it.

¹ In Essay IV of *Totem and Taboo* (1912-13).

² E. D. Dekker (1820-87).

After these preliminaries we can return to our consideration of moral masochism. We have said that, by their behaviour during treatment and in life, the individuals in question give an impression of being morally inhibited to an excessive degree, of being under the domination of an especially sensitive conscience, although they are not conscious of any of this ultra-morality. On closer inspection, we can see the difference there is between an unconscious extension of morality of this kind and moral masochism. In the former, the accent falls on the heightened sadism of the super-ego to which the ego submits; in the latter, it falls on the ego's own masochism which seeks punishment, whether from the super-ego or from the parental powers outside. We may be forgiven for having confused the two to begin with; for in both cases it is a question of a relationship between the ego and the super-ego (or powers that are equivalent to it), and in both cases what is involved is a need which is satisfied by punishment and suffering. It can hardly be an insignificant detail, then, that the sadism of the super-ego becomes for the most part glaringly conscious, whereas the masochistic trend of the ego remains as a rule concealed from the subject and has to be inferred from his behaviour.

The fact that moral masochism is unconscious leads us to an obvious clue. We were able to translate the expression 'unconscious sense of guilt' as meaning a need for punishment at the hands of a parental power. We now know that the wish, which so frequently appears in phantasies, to be beaten by the father stands very close to the other wish, to have a passive (feminine) sexual relation to him and is only a regressive distortion of it. If we insert this explanation into the content of moral masochism, its hidden meaning becomes clear to us. Conscience and morality have arisen through the overcoming, the desexualization, of the Oedipus complex; but through moral masochism morality becomes sexualized once more, the Oedipus complex is revived and the way is opened for a regression from morality to the Oedipus complex. This is to the advantage neither of morality nor of the person concerned. An individual may, it is true, have preserved the whole or some measure of ethical sense alongside of his masochism; but, alternatively, a large part of his conscience may have vanished into his masochism. Again, masochism creates a temptation to perform 'sinful' actions, which must then be expiated by the reproaches of the sadistic conscience (as is exemplified in so many Russian character-types) or by chastisement from the great parental power of Destiny. In order to provoke punishment from this last representative of the parents, the masochist must do what is inexpedient, must act against his own interests, must ruin the prospects which open out to him in the real world and must, perhaps, destroy his own real existence.

The turning back of sadism against the self regularly occurs where a *cultural suppression of the instincts* holds back a large part of the subject's destructive instinctual components from being exercised in life. We may suppose that this portion of the destructive instinct which has retreated appears in the ego as an intensification of masochism. The phenomena of conscience, however, lead us to infer that the destructiveness which returns from the external world is also taken up by the super-ego, without any such transformation, and increases its sadism against the ego. The sadism of the super-ego and the masochism of the ego supplement each other and unite to produce the same effects. It is only in this way, I think, that we can understand how the suppression of an instinct can - frequently or quite generally - result in a sense of guilt and how a person's conscience becomes more severe and more sensitive the more he refrains from aggression against others. One might expect that if a man knows that he is in the habit of avoiding the commission of acts of aggression that are undesirable from a cultural standpoint he will for that reason have a good conscience and will watch over his ego less suspiciously. The situation is usually presented as though ethical requirements were the primary thing and the renunciation of instinct followed from them. This leaves the origin of the ethical sense unexplained. Actually, it seems to be the other way about. The first instinctual renunciation is enforced by external powers, and it is only this which creates the ethical sense, which expresses itself in conscience and demands a further renunciation of instinct.

Thus moral masochism becomes a classical piece of evidence for the existence of fusion of instinct. Its danger lies in the fact that it originates from the death instinct and corresponds to the part of that instinct which has escaped being turned outwards as an instinct of destruction. But since, on the other hand, it has the significance of an erotic component, even the subject's destruction of himself cannot take place without libidinal satisfaction.

THE DISSOLUTION OF THE OEDIPUS COMPLEX
(1924)

Intentionally left blank

THE DISSOLUTION OF THE OEDIPUS COMPLEX

To an ever-increasing extent the Oedipus complex reveals its importance as the central phenomenon of the sexual period of early childhood. After that, its dissolution takes place; it succumbs to repression, as we say, and is followed by the latency period. It has not yet become clear, however, what it is that brings about its destruction. Analyses seem to show that it is the experience of painful disappointments. The little girl likes to regard herself as what her father loves above all else; but the time comes when she has to endure a harsh punishment from him and she is cast out of her fool's paradise. The boy regards his mother as his own property; but he finds one day that she has transferred her love and solicitude to a new arrival. Reflection must deepen our sense of the importance of those influences, for it will emphasize the fact that distressing experiences of this sort, which act in opposition to the content of the complex, are inevitable. Even when no special events occur, like those we have mentioned as examples, the absence of the satisfaction hoped for, the continued denial of the desired baby, must in the end lead the small lover to turn away from his hopeless longing. In this way the Oedipus complex would go to its destruction from its lack of success, from the effects of its internal impossibility.

Another view is that the Oedipus complex must collapse because the time has come for its disintegration, just as the milk-teeth fall out when the permanent ones begin to grow. Although the majority of human beings go through the Oedipus complex as an individual experience, it is nevertheless a phenomenon which is determined and laid down by heredity and which is bound to pass away according to programme when the next pre-ordained phase of development sets in. This being so, it is of no great importance what the occasions are which allow this to happen, or, indeed, whether any such occasions can be discovered at all.

The justice of both these views cannot be disputed. Moreover, they are compatible. There is room for the ontogenetic view side by side with the more far-reaching phylogenetic one. It is also true that even at birth the whole individual is destined to die, and perhaps his organic disposition may already contain the indication of what he is to die from. Nevertheless, it remains of interest to follow out how this innate programme is carried out and in what way accidental noxae exploit his disposition.

We have lately been made more clearly aware than before that a child's sexual development advances to a certain phase at which the genital organ has already taken over the leading role. But this genital is the male one only, or, more correctly, the penis; the female genital has remained undiscovered. This phallic phase, which is contemporaneous with the Oedipus complex, does not develop further to the definitive genital organization, but is submerged, and is succeeded by the latency period. Its termination, however, takes place in a typical manner and in conjunction with events that are of regular recurrence.

When the (male) child's interest turns to his genitals he betrays the fact by manipulating them frequently; and he then finds that the adults do not approve of this behaviour. More or less plainly, more or less brutally, a threat is pronounced that this part of him which he values so highly will be taken away from him. Usually it is from women that the threat emanates; very often they seek to strengthen their authority by a reference to the father or the doctor, who, so they say, will carry out the punishment. In a number of cases the women will themselves mitigate the threat in a symbolic manner by telling the child that what is to be removed is not his genital, which actually plays a passive part, but his hand, which is the active culprit. It happens particularly often that the little boy is threatened with castration, not because he plays with his penis with his hand, but because he wets his bed every night and cannot be got to be clean. Those in charge of him behave as if this nocturnal incontinence was the result and the proof of his being unduly concerned with his penis, and they are probably right. In any case, long-continued bed-wetting is to be equated with the emissions of adults. It is an expression of the same excitation of the genitals which has impelled the child to masturbate at this period.

Now it is my view that what brings about the destruction of the child's phallic genital organization is this threat of castration. Not immediately, it is true, and not without other influences being brought to bear as well. For to begin with the boy does not believe in the threat or obey it in the least. Psycho-analysis has recently attached importance to two experiences which all children go through and which, it is suggested, prepare them for the loss of highly valued parts of the body. These experiences are the withdrawal of the mother's breast - at first intermittently and later for good - and the daily demand on them to give up the contents of the bowel. But there is no evidence to show that, when the threat of castration takes place, those experiences have any effect. It is not until a *fresh* experience comes his way that the child begins to reckon with the possibility of being castrated, and then only hesitatingly and unwillingly, and not without making efforts to depreciate the significance of something he has himself observed.

The observation which finally breaks down his unbelief is the sight of the female genitals. Sooner or later the child, who is so proud of his possession of a penis, has a view of the genital region of a little girl, and cannot help being convinced of the absence of a penis in a creature who is so like himself. With this, the loss of his own penis becomes imaginable, and the threat of castration takes its deferred effect.

We should not be as short-sighted as the person in charge of the child who threatens him with castration, and we must not overlook the fact that at this time masturbation by no means represents the whole of his sexual life. As can be clearly shown, he stands in the Oedipus attitude to his parents; his masturbation is only a genital discharge of the sexual excitation belonging to the complex, and throughout his later years will owe its importance to that relationship. The Oedipus complex offered the child two possibilities of satisfaction, an active and a passive one. He could put himself in his father's place in a masculine fashion and have intercourse with his mother as his father did, in which case he would soon have felt the latter as a hindrance; or he might want to take the place of his mother and be loved by his father, in which case his mother would become superfluous. The child may have had only very vague notions as to what constitutes a satisfying erotic intercourse; but certainly the penis must play a part in it, for the sensations in his own organ were evidence of that. So far he had had no occasion to doubt that women possessed a penis. But now his acceptance of the possibility of castration, his recognition that women were castrated, made an end of both possible ways of obtaining satisfaction from the Oedipus complex. For both of them entailed the loss of his penis - the masculine one as a resulting punishment and the feminine one as a precondition. If the satisfaction of love in the field of the Oedipus complex is to cost the child his penis, a conflict is bound to arise between his narcissistic interest in that part of his body and the libidinal cathexis of his parental objects. In this conflict the first of these forces normally triumphs: the child's ego turns away from the Oedipus complex.

I have described elsewhere how this turning away takes place. The object-cathexes are given up and replaced by identifications. The authority of the father or the parents is introjected into the ego, and there it forms the nucleus of the super-ego, which takes over the severity of the father and perpetuates his prohibition against incest, and so secures the ego from the return of the libidinal object-cathexis. The libidinal trends belonging to the Oedipus complex are in part desexualized and sublimated (a thing which probably happens with every transformation into an identification) and in part inhibited in their aim and changed into impulses of affection. The whole process has, on the one hand, preserved the genital organ - has averted the danger of its loss - and, on the other, has paralysed it - has removed its function. This process ushers in the latency period, which now interrupts the child's sexual development.

I see no reason for denying the name of a 'repression' to the ego's turning away from the Oedipus complex, although later repressions come about for the most part with the participation of the super-ego, which in this case is only just being formed. But the process we have described is more than a repression. It is equivalent, if it is ideally carried out, to a destruction and an abolition of the complex. We may plausibly assume that we have here come upon the borderline - never a very sharply drawn one - between the normal and the pathological. If the ego has in fact not achieved much more than a *repression* of the complex, the latter persists in an unconscious state in the id and will later manifest its pathogenic effect.

Analytic observation enables us to recognize or guess these connections between the phallic organization, the Oedipus complex, the threat of castration, the formation of the super-ego and the latency period. These connections justify the statement that the destruction of the Oedipus complex is brought about by the threat of castration. But this does not dispose of the problem; there is room for a theoretical speculation which may upset the results we have come to or put them in a new light. Before we start along this new path, however, we must turn to a question which has arisen in the course of this discussion and has so far been left on one side. The process which has been described refers, as has been expressly said, to male children only. How does the corresponding development take place in little girls?

At this point our material - for some incomprehensible reason - becomes far more obscure and full of gaps. The female sex, too, develops an Oedipus complex, a super-ego and a latency period. May we also attribute a phallic organization and a castration complex to it? The answer is in the affirmative; but these things cannot be the same as they are in boys. Here the feminist demand for equal rights for the sexes does not take us far, for the morphological distinction is bound to find expression in differences of psychological development. 'Anatomy is Destiny', to vary a saying of Napoleon's. The little girl's clitoris behaves just like a penis to begin with; but, when she makes a comparison with a playfellow of the other sex, she perceives that she has 'come off badly' and she feels this as a wrong done to her and as a ground for inferiority. For a while still she consoles herself with the expectation that later on, when she grows older, she will acquire just as big an appendage as the boy's. Here the masculinity complex of women branches off. A female child, however, does not understand her lack of a penis as being a sex character; she explains it by assuming that at some earlier date she had possessed an equally large organ and had then lost it by castration. She seems not to extend this inference from herself to other, adult females, but, entirely on the lines of the phallic phase, to regard them as possessing large and complete - that is to say, male - genitals. The essential difference thus comes about that the girl accepts castration as an accomplished fact, whereas the boy fears the possibility of its occurrence.

The fear of castration being thus excluded in the little girl, a powerful motive also drops out for the setting-up of a super-ego and for the breaking-off of the infantile genital organization. In her, far more than in the boy, these changes seem to be the result of upbringing and of intimidation from outside which threatens her with a loss of love. The girl's Oedipus complex is much simpler than that of the small bearer of the penis; in my experience, it seldom goes beyond the taking of her mother's place and the adopting of a feminine attitude towards her father. Renunciation of the penis is not tolerated by the girl without some attempt at compensation. She slips - along the line of a symbolic equation, one might say - from the penis to a baby. Her Oedipus complex culminates in a desire, which is long retained, to receive a baby from her father as a gift - to bear him a child. One has an impression that the Oedipus complex is then gradually given up because this wish is never fulfilled. The two wishes - to possess a penis and a child - remain strongly cathected in the unconscious and help to prepare the female creature for her later sexual role. The comparatively lesser strength of the sadistic contribution to her sexual instinct, which we may no doubt connect with the stunted growth of her penis, makes it easier in her case for the direct sexual trends to be transformed into aim-inhibited trends of an affectionate kind. It must be admitted, however, that in general our insight into these developmental processes in girls is unsatisfactory, incomplete and vague.

I have no doubt that the chronological and causal relations described here between the Oedipus complex, sexual intimidation (the threat of castration), the formation of the super-ego and the beginning of the latency period are of a typical kind; but I do not wish to assert that this type is the only possible one. Variations in the chronological order and in the linking-up of these events are bound to have a very important bearing on the development of the individual.

Since the publication of Otto Rank's interesting study, *The Trauma of Birth*, even the conclusion arrived at by this modest investigation, to the effect that the boy's Oedipus complex is destroyed by the fear of castration, cannot be accepted without further discussion. Nevertheless, it seems to me premature to enter into such a discussion at the present time, and perhaps inadvisable to begin a criticism or an appreciation of Rank's view at this juncture.

THE LOSS OF REALITY IN NEUROSIS AND PSYCHOSIS
(1924)

Intentionally left blank

THE LOSS OF REALITY IN NEUROSIS AND PSYCHOSIS

I have recently¹ indicated as one of the features which differentiate a neurosis from a psychosis the fact that in a neurosis the ego, in its dependence on reality, suppresses a piece of the id (of instinctual life), whereas in a psychosis, this same ego, in the service of the id, withdraws from a piece of reality. Thus for a neurosis the decisive factor would be the predominance of the influence of reality, whereas for a psychosis it would be the predominance of the id. In a psychosis, a loss of reality would necessarily be present, whereas in a neurosis, it would seem, this loss would be avoided.

But this does not at all agree with the observation which all of us can make that every neurosis disturbs the patient's relation to reality in some way, that it serves him as a means of withdrawing from reality, and that, in its severe forms, it actually signifies a flight from real life. This contradiction seems a serious one; but it is easily resolved, and the explanation of it will in fact help us to understand neuroses.

For the contradiction exists only as long as we keep our eyes fixed on the situation at the *beginning* of the neurosis, in which the ego, in the service of reality, sets about the repression of an instinctual impulse. This, however, is not yet the neurosis itself. The neurosis consists rather in the processes which provide a compensation for the portion of the id that has been damaged - that is to say, in the reaction against the repression and in the failure of the repression. The loosening of the relation to reality is a consequence of this second step in the formation of a neurosis, and it ought not to surprise us if a detailed examination shows that the loss of reality affects precisely that piece of reality as a result of whose demands the instinctual repression ensued.

There is nothing new in our characterization of neurosis as the result of a repression that has failed. We have said this all along, and it is only because of the new context in which we are viewing the subject that it has been necessary to repeat it.

¹ 'Neurosis and Psychosis' (1924*b*)

Incidentally, the same objection arises in a specially marked manner when we are dealing with a neurosis in which the exciting cause (the 'traumatic scene') is known, and in which one can see how the person concerned turns away from the experience and consigns it to amnesia. Let me go back by way of example to a case analysed a great many years ago,¹ in which the patient, a young woman, was in love with her brother-in-law. Standing beside her sister's death-bed, she was horrified at having the thought: 'Now he is free and can marry me.' This scene was instantly forgotten, and thus the process of regression, which led to her hysterical pains, was set in motion. It is instructive precisely in this case, moreover, to learn along what path the neurosis attempted to solve the conflict. It took away from the value of the change that had occurred in reality, by repressing the instinctual demand which had emerged - that is, her love for her brother-in-law. The *psychotic* reaction would have been a disavowal of the fact of her sister's death.

We might expect that when a psychosis comes into being, something analogous to the process in a neurosis occurs, though, of course, between different agencies of the mind; thus we might expect that in a psychosis, too, two steps could be discerned, of which the first would drag the ego away, this time from reality, while the second would try to make good the damage done and re-establish the subject's relations to reality at the expense of the id. And, in fact, some analogy of the sort can be observed in a psychosis. Here, too, there are two steps, the second of which has the character of a reparation. But beyond that the analogy gives way to a far more extensive similarity between the two processes. The second step of the psychosis is indeed intended to make good the loss of reality, not, however, at the expense of a restriction of the id - as happens in neurosis at the expense of the relation to reality - but in another, more autocratic manner, by the creation of a new reality which no longer raises the same objections as the old one that has been given up. The second step, therefore, both in neurosis and psychosis, is supported by the same trends. In both cases it serves the desire for power of the id, which will not allow itself to be dictated to by reality. Both neurosis and psychosis are thus the expression of a rebellion on the part of the id against the external world, of its unwillingness - or, if one prefers, its incapacity - to adapt itself to the exigencies of reality, to *Ανάγκη* [Necessity]. Neurosis and psychosis differ from each other far more in their first, introductory, reaction than in the attempt at reparation which follows it.

¹ In *Studies on Hysteria* (1895d).

Accordingly, the initial difference is expressed thus in the final outcome: in neurosis a piece of reality is avoided by a sort of flight, whereas in psychosis it is remodelled. Or we might say: in psychosis, the initial flight is succeeded by an active phase of remodelling; in neurosis, the initial obedience is succeeded by a deferred attempt at flight. Or again, expressed in yet another way: neurosis does not disavow the reality, it only ignores it; psychosis disavows it and tries to replace it. We call behaviour 'normal' or 'healthy', if it combines certain features of both reactions - if it disavows the reality as little as does a neurosis, but if it then exerts itself, as does a psychosis, to effect an alteration of that reality. Of course, this expedient, normal, behaviour leads to work being carried out on the external world; it does not stop, as in psychosis, at effecting internal changes. It is no longer *autoplastic* but *alloplastic*.

In a psychosis, the transforming of reality is carried out upon the psychical precipitates of former relations to it - that is, upon the memory-traces, ideas and judgements which have been previously derived from reality and by which reality was represented in the mind. But this relation was never a closed one; it was continually being enriched and altered by fresh perceptions. Thus the psychosis is also faced with the task of procuring for itself perceptions of a kind which shall correspond to the new reality; and this is most radically effected by means of hallucination. The fact that, in so many forms and cases of psychosis, the paramnesias, the delusions and the hallucinations that occur are of a most distressing character and are bound up with a generation of anxiety - this fact is without doubt a sign that the whole process of remodelling is carried through against forces which oppose it violently. We may construct the process on the model of a neurosis, with which we are more familiar. There we see that a reaction of anxiety sets in whenever the repressed instinct makes a thrust forward, and that the outcome of the conflict is only a compromise and does not provide complete satisfaction. Probably in a psychosis the rejected piece of reality constantly forces itself upon the mind, just as the repressed instinct does in a neurosis, and that is why in both cases the consequences too are the same. The elucidation of the various mechanisms which are designed, in the psychoses, to turn the subject away from reality and to reconstruct reality - this is a task for specialized psychiatric study which has not yet been taken in hand.

There is, therefore, a further analogy between a neurosis and a psychosis, in that in both of them the task which is undertaken in the second step is partly unsuccessful. For the repressed instinct is unable to procure a full substitute (in neurosis); and the representation of reality cannot be remoulded into satisfying forms (not, at least, in every species of mental illness). But the emphasis is different in the two cases. In a psychosis it falls entirely on the first step, which is pathological in itself and cannot but lead to illness. In a neurosis, on the other hand, it falls on the second step, on the failure of the repression, whereas the first step may succeed, and does succeed in innumerable instances without overstepping the bounds of health - even though it does so at a certain price and not without leaving behind traces of the psychical expenditure it has called for. These distinctions, and perhaps many others as well, are a result of the topographical difference in the initial situation of the pathogenic conflict - namely whether in it the ego yielded to its allegiance to the real world or to its dependence on the id.

A neurosis usually contents itself with avoiding the piece of reality in question and protecting itself against coming into contact with it. The sharp distinction between neurosis and psychosis, however, is weakened by the circumstance that in neurosis, too, there is no lack of attempts to replace a disagreeable reality by one which is more in keeping with the subject's wishes. This is made possible by the existence of a *world of phantasy*, of a domain which became separated from the real external world at the time of the introduction of the reality principle. This domain has since been kept free from the demands of the exigencies of life, like a kind of 'reservation'; it is not inaccessible to the ego, but is only loosely attached to it. It is from this world of phantasy that the neurosis draws the material for its new wishful constructions, and it usually finds that material along the path of regression to a more satisfying real past.

It can hardly be doubted that the world of phantasy plays the same part in psychosis and that there, too, it is the storehouse from which the materials or the pattern for building the new reality are derived. But whereas the new, imaginary external world of a psychosis attempts to put itself in the place of external reality, that of a neurosis, on the contrary, is apt, like the play of children, to attach itself to a piece of reality - a different piece from the one against which it has to defend itself - and to lend that piece a special importance and a secret meaning which we (not always quite appropriately) call a *symbolic* one. Thus we see that both in neurosis and psychosis there comes into consideration the question not only of a *loss of reality* but also of a *substitute for reality*.

A SHORT ACCOUNT OF PSYCHO-ANALYSIS
(1924)

Intentionally left blank

A SHORT ACCOUNT OF PSYCHO-ANALYSIS

I

Psycho-analysis may be said to have been born with the twentieth century; for the publication in which it emerged before the world as something new - my *Interpretation of Dreams* - bears the date '1900'. But, as may well be supposed, it did not drop from the skies ready-made. It had its starting-point in older ideas, which it developed further; it sprang from earlier suggestions, which it elaborated. Any history of it must therefore begin with an account of the influences which determined its origin and should not overlook the times and circumstances that preceded its creation.

Psycho-analysis grew up in a narrowly-restricted field. At the outset, it had only a single aim - that of understanding something of the nature of what were known as the 'functional' nervous diseases, with a view to overcoming the impotence which had so far characterized their medical treatment. The neurologists of that period had been brought up to have a high respect for chemico-physical and pathologico-anatomical facts; and they were latterly under the influence of the findings of Hitzig and Fritsch, of Ferrier, Goltz and others, who seemed to have established an intimate and possibly exclusive connection between certain functions and particular parts of the brain. They did not know what to make of the psychical factor and could not understand it. They left it to the philosophers, the mystics and - the quacks; and they considered it unscientific to have anything to do with it. Accordingly they could find no approach to the secrets of the neuroses, and in particular of the enigmatic 'hysteria', which was, indeed, the prototype of the whole species. As late as in 1885, when I was studying at the Salpêtrière, I found that people were content to account for hysterical paralyses by a formula which asserted that they were founded on slight functional disturbances of the same parts of the brain which, when they were severely damaged, led to the corresponding organic paralyses.

Of course this lack of understanding affected the *treatment* of these pathological conditions badly as well. In general this consisted in measures designed to 'harden' the patient - in the prescription of medicines and in attempts, mostly very ill-contrived and executed in an unfriendly manner, at bringing mental influences to bear on him by threats, jeers and warnings and by exhorting him to make up his mind to 'pull himself together'. Electrical treatment was given out as being a specific cure for nervous conditions; but anyone who has endeavoured to carry out Erb's detailed instructions must marvel at the space that phantasy can occupy even in what professes to be an exact science. The decisive turn was taken in the eighties, when the phenomena of hypnotism made one more attempt to find admission to medical science - this time with more success than so often before, thanks to the work of Liébeault, Bernheim, Heidenhain and Forel. The essential thing was that the genuineness of these phenomena was recognized. Once this had been admitted, two fundamental and unforgettable lessons could not fail to be drawn from hypnotism. First, one was given convincing proof that striking somatic changes could after all be brought about solely by mental influences, which in this case one had oneself set in motion. Secondly, one received the clearest impression - especially from the behaviour of subjects *after* hypnosis - of the existence of mental processes that one could only describe as 'unconscious'. The 'unconscious' had, it is true, long been under discussion among philosophers as a theoretical concept; but now for the first time, in the phenomena of hypnotism, it became something actual, tangible and subject to experiment. Apart from all this, hypnotic phenomena showed an unmistakable similarity to the manifestations of some neuroses.

It is not easy to over-estimate the importance of the part played by hypnotism in the history of the origin of psycho-analysis. From a theoretical as well as from a therapeutic point of view, psycho-analysis has at its command a legacy which it has inherited from hypnotism.

Hypnosis also proved a valuable aid in the study of the neuroses - once again, first and foremost, of hysteria. Charcot's experiments created a great impression. He suspected that certain paralyses which appeared after a trauma (an accident) were of a hysterical nature, and he showed that, by suggesting a trauma under hypnosis, he was able to provoke paralyses of the same sort artificially. The expectation was thus raised that traumatic influences might in all cases play a part in the production of hysterical symptoms. Charcot himself made no further efforts towards a psychological understanding of hysteria; but his pupil, Pierre Janet, took up the question and was able to show, with the help of hypnosis, that the symptoms of hysteria were firmly dependent on certain unconscious thoughts (*idées fixes*). Janet attributed to hysteria a supposed constitutional incapacity for holding mental processes together - an incapacity which led to a disintegration (dissociation) of mental life.

Psycho-analysis, however, was not in any way based on these researches of Janet's. The decisive factor in its case was the experience of a Viennese physician, Dr. Josef Breuer. In 1881, independently of any outside influence, he was able with the help of hypnosis to study and restore to health a highly-gifted girl who suffered from hysteria. Breuer's findings were not given to the public until fifteen years later, after he had taken the present writer (Freud) into collaboration. This case of Breuer's retains its unique significance for our understanding of the neuroses to this day; so that we cannot avoid dwelling on it a little longer. It is essential to realize clearly in what its peculiarity consisted. The girl had fallen ill while she was nursing her father, to whom she was tenderly attached. Breuer was able to establish that all her symptoms were related to this period of nursing and could be explained by it. Thus it had for the first time become possible to obtain a complete view of a case of this puzzling neurosis, and all its symptoms had turned out to have a meaning. Further, it was a universal feature of the symptoms that they had arisen in situations involving an impulse to an action which, however, had not been carried out but had for other reasons been suppressed. The symptoms had, in fact, appeared *in place of* the actions that were not performed. Thus, to explain the aetiology of hysterical symptoms, we were led to the subject's emotional life (to affectivity) and to the interplay of mental forces (to dynamics); and since then these two lines of approach have never been dropped.

The precipitating causes of the symptoms were compared by Breuer to Charcot's traumas. Now it was a remarkable fact that all these traumatic precipitating causes, and all the mental impulses starting from them, were lost to the patient's memory, as though they had never happened; while their products - the symptoms - persisted unaltered, as though, so far as they were concerned, there was no such thing as the effacing effect of time. Here, therefore, we had a fresh proof of the existence of mental processes which were unconscious but for that very reason especially powerful - processes which we had first come to know in post-hypnotic suggestion. The therapeutic procedure adopted by Breuer was to induce the patient, under hypnosis, to remember the forgotten traumas and to react to them with powerful expressions of affect. When this had been done, the symptom, which had till then taken the place of these expressions of emotion, disappeared. Thus one and the same procedure served simultaneously the purposes of investigating and of getting rid of the ailment; and this unusual conjunction was later retained in psycho-analysis.

After the present writer had, during the early nineties, confirmed Breuer's results in a considerable number of patients, the two, Breuer and Freud, together decided on a publication, *Studies on Hysteria* (1895d), which contained their findings and an attempt at a theory based on them. This asserted that hysterical symptoms arose when the affect of a mental process cathected with a strong affect was forcibly prevented from being worked over consciously in the normal way and was thus diverted into a wrong path. In cases of hysteria, according to this theory, the affect passed over into an unusual somatic innervation ('conversion'), but could be given another direction and got rid of ('abreacted'), if the experience were revived under hypnosis. The authors gave this procedure the name of 'catharsis' (purging, setting free of a strangulated affect).

The cathartic method was the immediate precursor of psycho-analysis; and, in spite of every extension of experience and of every modification of theory, is still contained within it as its nucleus. But it was no more than a new medical procedure for influencing certain nervous diseases, and nothing suggested that it might become a subject for the most general interest and for the most violent contradiction.

II

Soon after the publication of *Studies on Hysteria* the partnership between Breuer and Freud came to an end. Breuer, who was in reality a consultant in internal medicine, gave up treating nervous patients, and Freud devoted himself to the further perfection of the instrument left over to him by his elder collaborator. The technical novelties which he introduced and the discoveries which he made changed the cathartic method into psycho-analysis. The most momentous step, no doubt, was his determination to do without the assistance of hypnosis in his technical procedure. He did so for two reasons: first, because, in spite of a course of instruction with Bernheim at Nancy, he did not succeed in inducing hypnosis in a sufficient number of cases, and secondly, because he was dissatisfied with the therapeutic results of catharsis based on hypnosis. It is true that these results were striking and appeared after a treatment of short duration, but they turned out not to be permanent and to depend too much on the patient's personal relations with the physician. The abandonment of hypnosis made a breach in the course of development of the procedure up to then, and it meant a fresh start.

Hypnosis had, however, performed the service of restoring to the patient's memory what he had forgotten. It was necessary to find some other technique to replace it; and the idea occurred to Freud of substituting for it the method of 'free association'. That is to say, he pledged his patients to refrain from any conscious reflection and to abandon themselves, in a state of quiet concentration, to following the ideas which occurred to them spontaneously (involuntarily) - 'to skim off the surface of their consciousness'. They were to communicate these ideas to the physician even if they felt objections to doing so, if, for instance, the thoughts seemed too disagreeable, too senseless, too unimportant or irrelevant. The choice of free association as a means of investigating the forgotten unconscious material seems so strange that a word in justification of it will not be out of place. Freud was led to it by an expectation that the so-called 'free' association would prove in fact to be unfree, since, when all conscious intellectual purposes had been suppressed, the ideas that emerged would be seen to be determined by the unconscious material. This expectation was justified by experience. When the 'fundamental rule of psycho-analysis' which has just been stated was obeyed, the course of free association produced a plentiful store of ideas which could put one on the track of what the patient had forgotten. To be sure, this material did not bring up what had actually been forgotten, but it brought up such plain and numerous hints at it that, with the help of a certain amount of supplementing and interpreting, the doctor was able to guess (to reconstruct) the forgotten material from it. Thus free association together with the art of interpretation performed the same function as had previously been performed by hypnotism.

It looked as though our work had been made much more difficult and complicated; but the inestimable gain was that an insight was now obtained into an interplay of forces which had been concealed from the observer by the hypnotic state. It became evident that the work of uncovering what had been pathogenically forgotten had to struggle against a constant and very intense resistance. The critical objections which the patient raised in order to avoid communicating the ideas which occurred to him, and against which the fundamental rule of psycho-analysis was directed, had themselves already been manifestations of this resistance. A consideration of the phenomena of resistance led to one of the corner-stones of the psycho-analytic theory of the neuroses - the theory of repression. It was plausible to suppose that the same forces which were now struggling against the pathogenic material being made conscious had at an earlier time made the same efforts with success. A gap in the aetiology of neurotic symptoms was thus filled. The impressions and mental impulses, for which the symptoms were now serving as substitutes, had not been forgotten without reason or on account of a constitutional incapacity for synthesis (as Janet supposed); they had, though the influence of other mental forces, met with a repression the success and evidence of which was precisely their being debarred from consciousness and excluded from memory. It was only in consequence of this repression that they had become pathogenic - that is, had succeeded in manifesting themselves along unusual paths as symptoms.

A conflict between two groups of mental trends had to be looked on as the ground for repression and accordingly as the cause of every neurotic illness. And here experience taught us a new and surprising fact about the nature of the forces that were struggling against each other. Repression invariably proceeded from the sick person's conscious personality (his ego) and took its stand on aesthetic and ethical motives; the impulses that were subjected to repression were those of selfishness and cruelty, which can be summed up in general as evil, but above all sexual wishful impulses, often of the crudest and most forbidden kind. Thus the symptoms were a substitute for forbidden satisfactions and the illness seemed to correspond to an incomplete subjugation of the immoral side of human beings.

Advance in knowledge made ever clearer the enormous part played in mental life by sexual wishful impulses, and led to a detailed study of the nature and development of the sexual instinct.¹ But we also came upon another purely empirical finding, in the discovery that the experiences and conflicts of the first years of childhood play an unsuspectedly important part in the individual's development and leave behind them ineffaceable dispositions bearing upon the period of maturity. This led to the revelation of something that had hitherto been fundamentally overlooked by science - infantile sexuality, which, from the tenderest age onwards, is manifested both in physical reactions and in mental attitudes. In order to bring together this sexuality of children with what is described as the normal sexuality of adults and the abnormal sexual life of perverts, the concept of what was sexual had itself to be corrected and widened in a manner which could be justified by the evolution of the sexual instinct.

After hypnosis was replaced by the technique of free association, Breuer's cathartic procedure turned into psycho-analysis, which for more than a decade was developed by the author (Freud) alone. During that time psycho-analysis gradually acquired a theory which appeared to give a satisfactory account of the origin, meaning and purpose of neurotic symptoms and provided a rational basis for medical attempts at curing the complaint. I will once again enumerate the factors that go to make up this theory. They are: emphasis on instinctual life (affectivity), on mental dynamics, on the fact that even the apparently most obscure and arbitrary mental phenomena invariably have a meaning and a causation, the theory of psychical conflict and of the pathogenic nature of repression, the view that symptoms are substitutive satisfactions, the recognition of the aetiological importance of sexual life, and in particular of the beginnings of infantile sexuality. From a philosophical standpoint this theory was bound to adopt the view that the mental does not coincide with the conscious, that mental processes are in themselves unconscious and are only made conscious by the functioning of special organs (agencies or systems). By way of completing this list, I will add that among the affective attitudes of childhood the complicated emotional relation of children to their parents - what is known as the Oedipus complex - came into prominence. It became ever clearer that this was the nucleus of every case of neurosis, and in the patient's behaviour towards his analyst certain phenomena of his emotional transference emerged which came to be of great importance for theory and technique alike.

¹ Freud, *Three Essays on the Theory of Sexuality* (1905d)

In the form which it thus assumed, the psycho-analytic theory of the neuroses already contained a number of things which ran counter to accepted opinions and inclinations and which were calculated to provoke astonishment, repugnance and scepticism in outsiders: for instance, the attitude of psycho-analysis to the problem of the unconscious, its recognition of an infantile sexuality and the stress it laid on the sexual factor in mental life generally. But more was to follow.

III

In order to reach even half way to an understanding of how, in a hysterical girl, a forbidden sexual wish can change into a painful symptom, it had been necessary to make far-reaching and complicated hypotheses about the structure and functioning of the mental apparatus. There was an evident contradiction here between expenditure of effort and result. If the conditions postulated by psycho-analysis really existed, they were of a fundamental nature and must be able to find expression in other phenomena besides hysterical ones. But if this inference were correct, psycho-analysis would have ceased to be of interest only to neurologists; it could claim the attention of everyone to whom psychological research was of any importance. Its findings would not only have to be taken into account in the field of pathological mental life but could not be overlooked either in coming to an understanding of normal functioning.

Evidence of its being of use for throwing light on other than pathological mental activity was early forthcoming in connection with two kinds of phenomena: with the very frequent parapraxes that occur in everyday life - such as forgetting things, slips of the tongue, and mislaying objects - and with the dreams dreamt by healthy and psychically normal people. Small failures of functioning, like the temporary forgetting of normally familiar proper names, slips of the tongue and of the pen, and so on, had hitherto not been considered worthy of any explanation at all or were supposed to be accounted for by conditions of fatigue, by distraction of the attention, etc. The present writer then showed from many examples, in his book *The Psychopathology of Everyday Life* (1901*b*), that events of this kind have a meaning, and arise owing to a conscious intention being interfered with by another, suppressed or actually unconscious one. As a rule, quick reflection or a short analysis is enough to reveal the interfering influence. Owing to the frequency of such parapraxes as slips of the tongue, it became easy for anyone to convince himself from his own experience of the existence of mental processes which are not conscious, but which are nevertheless operative and which at least find expression as inhibitions and modifications of other, intended acts.

The analysis of dreams led further: it was brought to public notice by the present writer as early as in 1900 in *The Interpretation of Dreams*. This showed that dreams are constructed in just the same way as neurotic symptoms. Like them, they may appear strange and senseless; but, if we examine them by a technique which differs little from the free association used in psycho-analysis, we are led from their manifest content to a secret meaning, to the latent dream-thoughts. This latent meaning is always a wishful impulse which is represented as fulfilled at the moment of the dream. But, except in young children and under the pressure of imperative physical needs, this secret wish can never be expressed recognizably. It has first to submit to a distortion, which is the work of restrictive, censoring forces in the dreamer's ego. In this way the manifest dream, as it is remembered in waking life, comes about. It is distorted, to the pitch of being unrecognizable, by concessions made to the dream-censorship; but it can be revealed once more by analysis as an expression of a situation of satisfaction or as the fulfilment of a wish. It is a compromise between two conflicting groups of mental trends, just as we have found to be the case with hysterical symptoms. The formula which, at bottom, best meets the essence of the dream is this: a dream is a (disguised) fulfilment of a (repressed) wish. The study of the process which transforms the latent dream-wish into the manifest content of the dream - a process known as the 'dream-work' - has taught us the best part of what we know of unconscious mental life.

Now a dream is not a morbid symptom but a product of the normal mind. The wishes which it represents as fulfilled are the same as those which are repressed in neuroses. Dreams owe the possibility of their genesis merely to the favourable circumstance that during the state of sleep, which paralyzes man's power of movement, repression is mitigated into the dream-censorship. If, however, the process of dream-formation oversteps certain limits, the dreamer brings it to a stop and wakes up in a fright. Thus it is proved that the same forces and the same processes taking place between them operate in normal as in pathological mental life. From the date of *The Interpretation of Dreams* psycho-analysis had a twofold significance. It was not only a new method of treating the neuroses but it was also a new psychology; it claimed the attention not only of nerve-specialists but also of all those who were students of a mental science.

The reception given it in the scientific world was, however, no friendly one. For some ten years no one took any notice of Freud's works. About the year 1907 attention was drawn to psycho-analysis by a group of Swiss psychiatrists (Bleuler and Jung, in Zurich), and a storm of indignation, which was not precisely fastidious in its methods and arguments, thereupon broke out, particularly in Germany. In this, psycho-analysis was sharing the fate of many novelties which, after a certain lapse of time, have found general recognition. Nevertheless it lay in its nature that it should inevitably arouse particularly violent opposition. It wounded the prejudices of civilized humanity at some specially sensitive spots. It subjected every individual, as it were, to the analytic reaction, by uncovering what had by universal agreement been repressed into the unconscious; and in this way it forced its contemporaries to behave like patients who, under analytic treatment, above all else bring their resistances to the fore. It must also be admitted that it was no easy thing to become convinced of the correctness of the psycho-analytic theories, nor to obtain instruction in the practice of analysis.

The general hostility, however, did not succeed in preventing psycho-analysis from continuous expansion during the next decade in two directions: on the map, for interest in it was constantly cropping up in new countries, and in the field of the mental sciences, for it was constantly finding applications in new branches of knowledge. In 1909 President G. Stanley Hall invited Freud and Jung to give a series of lectures at Clark University in Worcester, Mass., of which he was the head and where they were given a friendly reception. Since then psycho-analysis has remained popular in America, although precisely in that country its name has been coupled with much superficiality and some abuses. As early as in 1911, Havelock Ellis was able to report that analysis was studied and practised, not only in Austria and Switzerland, but also in the United States, in England, India, Canada, and, no doubt, in Australia too.

It was in this period of struggle and of first blossoming, moreover, that the periodicals devoted exclusively to psycho-analysis were inaugurated. These were the *Jahrbuch für psychoanalytische und psychopathologische Forschungen* (1909-1914), directed by Bleuler and Freud and edited by Jung, which ceased publication at the outbreak of the World War, the *Zentralblatt für Psychoanalyse* (1911), edited by Adler and Stekel, which was soon replaced by the *Internationale Zeitschrift für Psychoanalyse* (1913, to-day in its tenth volume); further, since 1912, *Imago*, founded by Rank and Sachs, a periodical for the application of psycho-analysis to the mental sciences. The great interest taken in the subject by Anglo-American doctors was shown in 1913 by the founding of the still active *Psycho-Analytic Revue* by White and Jelliffe. Later, in 1920, *The International Journal of Psycho-Analysis*, intended specially for readers in England, made its appearance under the editorship of Ernest Jones. The Internationaler Psychoanalytischer Verlag and the corresponding English undertaking, The International Psycho-Analytical Press, brought out a continuous series of analytic publications under the name of the Internationale Psychoanalytische Bibliothek (International Psycho-Analytical Library). The literature of psycho-analysis is, of course, not to be found only in these periodicals, which are for the most part supported by psycho-analytic societies; it appears far and wide in a great number of places, in scientific and in literary publications. Among the periodicals of the Latin world which pay special attention to psycho-analysis the *Rivista de Psiquiatria*, edited by H. Delgado in Lima (Peru), may be specially mentioned.

An essential difference between this second decade of psycho-analysis and the first lay in the fact that the present writer was no longer its sole representative. A constantly growing circle of pupils and followers had collected around him, who devoted themselves first to the diffusion of the theories of psycho-analysis and then extended them, supplemented them and carried them deeper. In the course of years, several of these supporters, as was inevitable, seceded, took their own paths, or turned themselves into an opposition which seemed to threaten the continuity of the development of psycho-analysis. Between 1911 and 1913 C. G. Jung in Zurich and Alfred Adler in Vienna produced some stir by their attempts at giving new interpretations to the facts of analysis and their efforts at a diversion from the analytic standpoint. But it soon appeared that these secessions had effected no lasting damage. What temporary success they achieved was easily accounted for by the readiness of the mass of people to have themselves set free from the pressure of the demands of psycho-analysis by whatever path might be opened to them. The great majority of co-workers remained firm and continued their work along the lines indicated to them. We shall come on their names repeatedly in the short account below of the findings of psycho-analysis in the many and various fields of its application.

IV

The noisy rejection of psycho-analysis by the medical world could not deter its supporters from developing it, to begin with, along its original lines into a specialized pathology and treatment of the neuroses - a task which has not been completely accomplished even to-day. Its undeniable therapeutic success, which far exceeded any that had previously been achieved, constantly spurred them on to fresh efforts; while the difficulties which came to light as the material was examined more deeply led to profound alterations in the technique of analysis and to important corrections in its theoretical hypotheses and postulates.

In the course of this development, the technique of psycho-analysis has become as definite and as delicate as that of any other specialized branch of medicine. A failure to understand this fact has led to many abuses (particularly in England and America) because people who have acquired only a literary knowledge of psycho-analysis from reading consider themselves capable of undertaking analytic treatments without having received any special training. The consequences of such behaviour are damaging both to the science and to the patients and have brought much discredit upon psycho-analysis. The foundation of a first psycho-analytic out-patient clinic (by Max Eitingon in Berlin in 1920) has therefore become a step of high practical importance. This institute seeks on the one hand to make analytic treatment accessible to wide circles of the population and on the other hand undertakes the education of doctors to be practical analysts by a course of training which includes as a condition that the learner shall agree to be analysed himself.

Among the hypothetical concepts which enable the doctor to deal with the analytic material, the first to be mentioned is that of 'libido'. Libido means in psycho-analysis in the first instance the force (thought of as quantitatively variable and measurable) of the sexual instincts directed towards an object - 'sexual' in the extended sense required by analytic theory. Further study showed that it was necessary to set alongside this 'object-libido' a 'narcissistic' or 'ego-libido', directed to the subject's own ego; and the interaction of these two forces has enabled us to account for a great number of normal and abnormal processes in mental life. A rough distinction was soon made between what are known as the 'transference neuroses' and the narcissistic disorders. The former (hysteria and obsessional neurosis) are the objects proper of psycho-analytic treatment, while the others, the narcissistic neuroses, though they can, it is true, be examined by the help of analysis, offer fundamental difficulties to therapeutic influence. It is true that the libido theory of psycho-analysis is by no means complete and that its relation to a general theory of the instincts is not yet clear, for psycho-analysis is a young science, quite unfinished and in a stage of rapid development. Here, however, it should be emphatically pointed out how erroneous the charge of pan-sexualism is which is so often levelled at psycho-analysis. It seeks to show that psycho-analytic theory knows of no mental motive forces other than purely sexual ones and in doing so exploits popular prejudices by using the word 'sexual' not in its analytic but in its vulgar sense.

The psycho-analytic view would also have to include in narcissistic disorders all the ailments described in psychiatry as 'functional psychoses'. It could not be doubted that neuroses and psychoses are not separated by a hard and fast line, any more than health and neurosis; and it was plausible to explain the mysterious psychotic phenomena by the discoveries achieved on the neuroses, which had hitherto been equally incomprehensible. The present writer had himself, during the period of his isolation, made a case of paranoid illness partly intelligible by an analytic investigation and had pointed out in this unquestionable psychosis the same contents (complexes) and a similar interplay of forces as in the simple neuroses. Bleuler followed out the indications of what he called 'Freudian mechanisms' in a whole number of psychoses, and Jung won high opinions as an analyst at a single blow when, in 1907, he explained the most eccentric symptoms in the end-stages of dementia praecox from the individual life-histories of the patients. The comprehensive study of schizophrenia by Bleuler (1911) probably demonstrated once and for all the justification of a psycho-analytic angle of approach for the understanding of these psychoses.

In this way psychiatry became the first field to which psycho-analysis was applied and it has remained so ever since. The same research workers who have done most to deepen analytic knowledge of the neuroses, such as Karl Abraham in Berlin and Sándor Ferenczi in Budapest (to name only the most prominent), have also played a leading part in throwing analytic light on the psychoses. The conviction of the unity and intimate connection of all the disorders that present themselves as neurotic and psychotic phenomena is becoming more and more firmly established despite all the efforts of the psychiatrists. People are beginning to understand - best of all, perhaps, in America - that the psycho-analytic study of the neuroses is the only preparation for an understanding of the psychoses, and that psycho-analysis is destined to make possible a scientific psychiatry of the future which will not need to content itself with describing curious clinical pictures and unintelligible sequences of events and with tracing the influence of gross anatomical and toxic traumas upon a mental apparatus which is inaccessible to our knowledge.

V

But the importance of psycho-analysis for psychiatry would never have drawn the attention of the intellectual world to it or won it a place in *The History of our Times*. This result was brought about by the relation of psycho-analysis to normal, not to pathological, mental life. Originally, analytic research had indeed no other aim than to establish the determinants of the onset (the genesis) of a few morbid mental states. In the course of its efforts, however, it succeeded in bringing to light facts of fundamental importance, in actually creating a new psychology, so that it became obvious that the validity of such findings could not possibly be restricted to the sphere of pathology. We have seen already when it was that the decisive proof was produced of the correctness of this conclusion. It was when dreams were successfully interpreted by analytic technique - dreams, which are a part of the mental life of normal people and which yet may in fact be regarded as pathological products that can regularly appear under healthy conditions.

If the psychological discoveries gained from the study of dreams were firmly kept in view, only one further step was needed before psycho-analysis could be proclaimed as the theory of the deeper mental processes not directly accessible to consciousness - as a 'depth-psychology' - and before it could be applied to almost all the mental sciences. This step lay in the transition from the mental activity of individual men to the psychical functions of human communities and peoples - that is, from individual to group psychology; and many surprising analogies forced this transition upon us. It had been found, for instance, that in the deep strata of unconscious mental activity contraries are not distinguished from each other but are expressed by the same element. But already in 1884 Karl Abel the philologist had put forward the view (in his 'Über den Gegensinn der Urworte') that the oldest languages known to us treat contraries in the same way. Thus Ancient Egyptian, for example, had in the first instance only one word for 'strong' and 'weak', and not till later were the two sides of the antithesis distinguished by slight modifications. Even in the most modern languages clear relics of such antithetical meanings are to be found. So in German '*Boden*' means the highest as well as the lowest thing in the house; similarly in Latin '*altus*' means 'high' and 'deep'. Thus the equivalence of contraries in dreams is a universal archaic trait in human thinking.

To take an instance from another field. It is impossible to escape the impression of the perfect correspondence which can be discovered between the obsessive actions of certain obsessional patients and the religious observances of believers all over the world. Some cases of obsessional neurosis actually behave like a caricature of a private religion, so that it is tempting to liken the official religions to an obsessional neurosis that has been mitigated by becoming universalized. This comparison, which is no doubt highly objectionable to all believers, has nevertheless proved most fruitful psychologically. For psycho-analysis soon discovered in the case of obsessional neurosis what the forces are that struggle with one another in it till their conflicts find a remarkable expression in the ceremonial of obsessive actions. Nothing similar was suspected in the case of religious ceremonial until, by tracing back religious feeling to the relation with the father as its deepest root, it became possible to point to an analogous dynamic situation in that case too. This instance, moreover, may warn the reader that even in its application to non-medical fields psycho-analysis cannot avoid wounding cherished prejudices, touching upon deeply-rooted sensibilities and thus provoking enmities which have an essentially emotional basis.

If we may assume that the most general features of unconscious mental life (conflicts between instinctual impulses, repressions and substitutive satisfactions) are present everywhere, and if there is a depth-psychology which leads to a knowledge of those features, then we may reasonably expect that the application of psycho-analysis to the most varied spheres of human mental activity will everywhere bring to light important and hitherto unattainable results. In an exceedingly valuable study, Otto Rank and Hanns Sachs (1913) have tried to bring together what the work of psycho-analysts had been able to achieve up to that time towards fulfilling these expectations. Lack of space prevents me from attempting to complete their enumeration here. I can only select for mention the most important findings with the addition of a few details.

If we leave little-known internal urges out of account, we may say that the main motive force towards the cultural development of man has been real external exigency, which has withheld from him the easy satisfaction of his natural needs and exposed him to immense dangers. This external frustration drove him into a struggle with reality, which ended partly in adaptation to it and partly in control over it; but it also drove him into working and living in common with those of his kind, and this already involved a renunciation of a number of instinctual impulses which could not be satisfied socially. With the further advances of civilization the demands of repression also grew. Civilization is after all built entirely on renunciation of instinct, and every individual on his journey from childhood to maturity has in his own person to recapitulate this development of humanity to a state of judicious resignation. Psycho-analysis has shown that it is predominantly, though not exclusively, sexual instinctual impulses that have succumbed to this cultural suppression. One portion of them, however, exhibit the valuable characteristic of allowing themselves to be diverted from their immediate aims and of thus placing their energy at the disposal of cultural development in the form of 'sublimated' trends. But another portion persist in the unconscious as unsatisfied wishes and press for some, even if it is distorted, satisfaction.

We have seen that one part of human mental activity is directed towards obtaining control over the real external world. Psycho-analysis now tells us further that another, particularly highly-prized, part of creative mental work serves for the fulfilment of wishes - for the substitutive satisfaction of the repressed wishes which, from the days of childhood, live in the spirit of each of us, unsatisfied. Among these creations, whose connection with an incomprehensible unconscious was always suspected, are myths and works of imaginative writing and of art, and the researches of psycho-analysts have in fact thrown a flood of light on the fields of mythology, the science of literature, and the psychology of artists. It is enough to mention Otto Rank's work as an example. We have shown that myths and fairy tales can be interpreted like dreams, we have traced the convoluted paths that lead from the urge of the unconscious wish to its realization in a work of art, we have learnt to understand the emotional effect of a work of art on the observer, and in the case of the artist himself we have made clear his internal kinship with the neurotic as well as his distinction from him, and we have pointed out the connection between his innate disposition, his chance experiences and his achievements. The aesthetic appreciation of works of art and the elucidation of the artistic gift are, it is true, not among the tasks set to psycho-analysis. But it seems that psycho-analysis is in a position to speak the decisive word in all questions that touch upon the imaginative life of man.

And now, as a third point, psycho-analysis has shown us, to our growing astonishment, the enormously important part played by what is known as the 'Oedipus complex' - that is, the emotional relation of a child to its two parents - in the mental life of human beings. Our astonishment diminishes when we realize that the Oedipus complex is the psychical correlate of two fundamental biological facts: the long period of the human child's dependence, and the remarkable way in which its sexual life reaches a first climax in the third to fifth years of life, and then, after a period of inhibition, sets in again at puberty. And here, the discovery was made that a third and extremely serious part of human intellectual activity, the part which has created the great institutions of religion, law, ethics, and all forms of civic life, has as its fundamental aim the enabling of the individual to master his Oedipus complex and to divert his libido from its infantile attachments into the social ones that are ultimately desired. The applications of psycho-analysis to the science of religion and sociology (e. g. by the present writer, Theodor Reik and Oskar Pfister), which have led to these findings, are still young and insufficiently appreciated; but it cannot be doubted that further studies will only confirm the certainty of these important conclusions.

By way, as it were, of postscript, I must also mention that educationists, too, cannot avoid making use of the hints which they have received from the analytic exploration of the mental life of children; and further that voices have been raised among therapists (e.g. Groddeck and Jelliffe), maintaining that the psycho-analytic treatment of serious organic complaints shows promising results, since in many of these affections some part is played by a psychical factor on which it is possible to bring influence to bear.

Thus we may express our expectation that psycho-analysis, whose development and achievements hitherto have been briefly and inadequately related in these pages, will enter into the cultural development of the next decades as a significant ferment, and will help to deepen our understanding of the world and to fight against some things in life which are recognized as injurious. It must not be forgotten, however, that psycho-analysis alone cannot offer a complete picture of the world. If we accept the distinction which I have recently proposed of dividing the mental apparatus into an ego, turned towards the external world and equipped with consciousness, and an unconscious id, dominated by its instinctual needs, then psycho-analysis is to be described as a psychology of the id (and of its effects upon the ego). In each field of knowledge, therefore, it can make only *contributions*, which require to be completed from the psychology of the ego. If these contributions often contain the essence of the facts, this only corresponds to the important part which, it may be claimed, is played in our lives by the mental unconscious that has so long remained unknown.

THE RESISTANCES TO PSYCHO-ANALYSIS
(1925)

Intentionally left blank

THE RESISTANCES TO PSYCHO-ANALYSIS

A child in his nurse's arms will turn away screaming at the sight of a strange face; a pious man will begin the new season with a prayer and he will also greet the first fruits of the year with a blessing; a peasant will refuse to buy a scythe unless it bears the trade-mark that was familiar to his parents. The distinction between these situations is obvious and would seem to justify one in looking for a different motive in each of them.

Nevertheless, it would be a mistake to overlook what they have in common. In each case we are dealing with unpleasure of the same kind. The child expresses it in an elementary fashion, the pious man lulls it by an artifice, while the peasant uses it as the motive for a decision. The source of this unpleasure is the demand made upon the mind by anything that is *new*, the psychical expenditure that it requires, the uncertainty, mounting up to anxious expectancy, which it bring along with it. It would be interesting to devote a whole study to mental reactions to novelty; for under certain, no longer primary, conditions we can observe behaviour of the contrary kind - a thirst for stimulation which flings itself upon anything that is new merely because it *is* new.

In scientific affairs there should be no place for recoiling from novelty. Science, in her perpetual incompleteness and insufficiency, is driven to hope for her salvation in new discoveries and new ways of regarding things. She does well, in order not to be deceived, to arm herself with scepticism and to accept nothing new unless it has withstood the strictest examination. Sometimes, however, this scepticism shows two unexpected features; it may be sharply directed against what is new while it spares what is familiar and accepted, and it may be content to reject things before it has examined them. But in behaving thus it reveals itself as a prolongation of the primitive reaction against what is new and as a cloak for the retention of that reaction. It is a matter of common knowledge how often in the history of scientific research it has happened that innovations have met with intense and stubborn resistance, while subsequent events have shown that the resistance was unjustified and that the novelty was valuable and important. What provoked the resistance was, as a rule, certain factors in the subject-matter of the novelty, while, on the other side, several factors must have combined to make the irruption of the primitive reaction possible.

A particularly bad reception was accorded to psycho-analysis, which the present writer began to develop nearly thirty years ago from the discoveries of Josef Breuer (of Vienna) on the origin of neurotic symptoms. It cannot be disputed that it possessed the quality of novelty, even though it made use of plenty of material which was well known from other sources (quite apart from Breuer's discoveries), such as the lessons from the teachings of Charcot, the great neuropathologist, and impressions derived from the sphere of hypnotic phenomena. Its original significance was purely therapeutic: it aimed at creating a new and efficient method for treating neurotic illnesses. But connections which could not be foreseen in the beginning caused psycho-analysis to reach out far beyond its original aim. It ended by claiming to have set our whole view of mental life upon a new basis and therefore to be of importance for every field of knowledge that is founded on psychology. After a decade of complete neglect it suddenly became a subject of general interest - and set loose a storm of indignant opposition.

The *forms* in which the resistance to psycho-analysis found expression need not now be considered. It is enough to say that the struggle over this innovation is by no means at an end, though it is already possible to see what direction it will take. Its opponents have not succeeded in suppressing the movement. Psycho-analysis, of which twenty years ago I was the only spokesman, has since attracted the support of numerous valuable and active workers, medical and non-medical, who make use of it as a procedure for the treatment of nervous diseases, as a method of psychological research and as an auxiliary instrument for scientific work in the most various departments of intellectual life. In the following pages our interest will be directed only to the *motives* of the resistance to psycho-analysis, with particular stress upon the composite character of that resistance and upon the differing amount of weight carried by its components.

From a clinical standpoint the neuroses must necessarily be put alongside the intoxications and such disorders as Graves' disease. These are conditions arising from an excess or a relative lack of certain highly active substances, whether produced inside the body or introduced into it from outside - in short, they are disturbances of the chemistry of the body, toxic conditions. If someone succeeded in isolating and demonstrating the hypothetical substance or substances concerned in neuroses, he would have no need to worry about opposition from the medical profession. For the present, however, no such avenue of approach to the problem is open. At the moment we can only start from the symptoms presented by a neurosis - symptoms which in the case of hysteria, for instance, consist of a combination of somatic and mental disturbances. Now Charcot's experiments as well as Breuer's clinical observations taught us that the somatic symptoms of hysteria are psychogenic too - that is, that they are precipitates of mental processes that have run their course. By putting a subject into a state of hypnosis it was possible at will to produce the somatic symptoms of hysteria artificially.

Psycho-analysis took hold of this new realization and began to consider the problem of the nature of the psychical processes which led to these unusual consequences. But the direction taken by this enquiry was not to the liking of the contemporary generation of physicians. They had been brought up to respect only anatomical, physical and chemical factors. They were not prepared for taking psychical ones into account and therefore met them with indifference or antipathy. They obviously had doubts whether psychical events allowed of any exact scientific treatment whatever. As an excessive reaction against an earlier phase during which medicine had been dominated by what was known as the 'philosophy of Nature', they regarded such abstractions as those with which psychology is obliged to work as nebulous, fantastic and mystical; while they simply refused to believe in remarkable phenomena which might have been the starting-point of research. The symptoms of hysterical neuroses were looked upon as shamming and the phenomena of hypnotism as a hoax. Even the psychiatrists, upon whose attention the most unusual and astonishing mental phenomena were constantly being forced, showed no inclination to examine their details or enquire into their connections. They were content to classify the variegated array of symptoms and trace them back, so far as they could manage, to somatic, anatomical or chemical aetiological disturbances. During this materialistic or, rather, mechanistic period, medicine made tremendous advances, but it also showed a short-sighted misunderstanding of the most important and most difficult among the problems of life.

It is easy to understand why doctors, with an attitude of this kind towards the mind, should have had no liking for psycho-analysis and should have demurred to its demand for learning many things afresh and for seeing many things in a different light. But as a compensation it might be supposed that the new theory would be all the more likely to meet with applause from philosophers. For philosophers were accustomed to putting abstract concepts (or, as unkind tongues would say, hazy words) in the forefront of their explanations of the universe, and it would be impossible that they should object to the extension of the sphere of psychology for which psycho-analysis had paved the way. But here another obstacle arose. The philosophers' idea of what is mental was not that of psycho-analysis. The overwhelming majority of philosophers regard as mental only the phenomena of consciousness. For them the world of consciousness coincides with the sphere of what is mental. Everything else that may take place in the 'mind' - an entity so hard to grasp - is relegated by them to the organic determinants of mental processes or to processes parallel to mental ones. Or, more strictly speaking, the mind has no contents other than the phenomena of consciousness, and consequently psychology, the science of the mind, has no other subject-matter. And on this point the layman's view is the same.

What, then, can a philosopher say to a theory which, like psycho-analysis, asserts that on the contrary what is mental is in itself *unconscious* and that being conscious is only a *quality*, which may or may not accrue to a particular mental act and the withholding of which may perhaps alter that act in no other respect? He will naturally say that anything both unconscious and mental would be an impossibility, a *contradictio in adjecto*, and he will fail to observe that in making this judgement he is merely repeating his own definition of what is mental, a definition which may perhaps be too narrow. It is easy for philosophers to feel this certainty, since they have no acquaintance with the material whose investigation has compelled analysts to believe in unconscious mental acts. Philosophers have never taken account of hypnosis, they have not concerned themselves with the interpreting of dreams - on the contrary, like doctors, they regard dreams as the meaningless products of reduced mental activity during sleep - they are scarcely aware that there are such things as obsessions and delusions and they would find themselves in a most embarrassing situation if they were asked to explain them on the basis of their own psychological premisses. Analysts, too, refuse to say what the unconscious is, but they can indicate the domain of phenomena whose observation has obliged them to assume its existence. Philosophers, who know no kind of observation other than self-observation, cannot follow them into that domain.

So it comes about that psycho-analysis derives nothing but disadvantages from its middle position between medicine and philosophy. Doctors regard it as a speculative system and refuse to believe that, like every other natural science, it is based on a patient and tireless elaboration of facts from the world of perception; philosophers, measuring it by the standard of their own artificially constructed systems, find that it starts from impossible premisses and reproach it because its most general concepts (which are only now in process of evolution) lack clarity and precision.

This state of affairs is enough to account for the reluctant and hesitant reception of analysis in scientific quarters. But it does not explain the outbursts of indignation, derision and scorn which, in disregard of every standard of logic and good taste, have characterized the controversial methods of its opponents. A reaction of such a kind suggests that resistances other than purely intellectual ones were stirred up and that powerful emotional forces were aroused. And there are indeed plenty of things to be found in the theory of psycho-analysis calculated to produce such an effect as this upon the passions of men of every kind and not of scientists alone. Above all there is the very important place in the mental life of human beings which psycho-analysis assigns to what are known as the sexual instincts. Psycho-analytic theory maintained that the symptoms of neuroses are distorted substitutive satisfactions of sexual instinctual forces, the direct satisfaction of which has been frustrated by internal resistances. Later on, when analysis had extended beyond its original field of work and began to be applied to normal mental life, it sought to show that these same sexual components, which could be diverted from their immediate aims and directed to other things, made the most important contributions to the cultural achievements of the individual and of society. These views were not entirely new. The incomparable significance of sexual life had been proclaimed by the philosopher Schopenhauer in an intensely impressive passage. Moreover, what psycho-analysis called sexuality was by no means identical with the impulsion towards a union of the two sexes or towards producing a pleasurable sensation in the genitals; it had far more resemblance to the all-inclusive and all-preserving Eros of Plato's *Symposium*.

But the opponents of psycho-analysis forgot its illustrious forerunners; they fell upon it as though it had made an assault upon the dignity of the human race. They accused it of 'pan-sexualism', though the psycho-analytic theory of the instincts had always been strictly dualistic and had at no time failed to recognize, alongside the sexual instincts, others to which it actually ascribed force enough to suppress the sexual instincts. (These mutually opposing forces were described to begin with as the sexual instincts and the ego instincts. A later theoretical development changed them into Eros and the instinct of death or destruction.) The suggestion that art, religion and social order originated in part in a contribution from the sexual instincts was represented by the opponents of analysis as a degradation of the highest cultural values. They emphatically declared that men have other interests besides this eternal one of sex, overlooking in their zeal the fact that animals too have other interests - indeed they are subject to sexuality, not permanently like men, but only in bouts occurring at specific periods - overlooking, too, the fact that the existence of these other interests in men had never been disputed and that nothing can be altered in the value of a cultural achievement by its being shown to have been derived from elementary animal instinctual sources.

Such a display of unfairness and lack of logic cries out for an explanation. Its origin is not hard to find. Human civilization rests upon two pillars, of which one is the control of natural forces and the other the restriction of our instincts. The ruler's throne rests upon fettered slaves. Among the instinctual components which are thus brought into service, the sexual instincts, in the narrower sense of the word, are conspicuous for their strength and savagery. Woe, if they should be set loose! The throne would be overturned and the ruler trampled under foot. Society is aware of this - and will not allow the topic to be mentioned.

But why not? What harm could the discussion do? Psycho-analysis has never said a word in favour of unfettering instincts that would injure our community; on the contrary it has issued a warning and an exhortation to us to mend our ways. But society refuses to consent to the ventilation of the question, because it has a bad conscience in more than one respect. In the first place it has set up a high ideal of morality - morality being restriction of the instincts - and insists that all its members shall fulfil that ideal without troubling itself with the possibility that obedience may bear heavily upon the individual. Nor is it sufficiently wealthy or well-organized to be able to compensate the individual for the amount of his instinctual renunciation. It is consequently left to the individual to decide how he can obtain, for the sacrifice he has made, enough compensation to enable him to preserve his mental balance. On the whole, however, he is obliged to live psychologically beyond his means, while the unsatisfied claims of his instincts make him feel the demands of civilization as a constant pressure upon him. Thus society maintains a condition of *cultural hypocrisy* which is bound to be accompanied by a sense of insecurity and a necessity for guarding what is an undeniably precarious situation by forbidding criticism and discussion. This line of thought holds good for all the instinctual impulses, including, therefore, the egoistic ones. The question whether it applies to all possible forms of civilization, and not merely to those which have evolved hitherto, cannot be discussed here. As regards the sexual instincts in the narrower sense, there is the further point that in most people they are tamed insufficiently and in a manner which is psychologically wrong and are therefore readier than the rest to break loose.

Psycho-analysis has revealed the weaknesses of this system and has recommended that it should be altered. It proposes that there should be a reduction in the strictness with which instincts are repressed and that correspondingly more play should be given to truthfulness. Certain instinctual impulses, with whose suppression society has gone too far, should be permitted a greater amount of satisfaction; in the case of certain others the inefficient method of suppressing them by means of repression should be replaced by a better and securer procedure. As a result of these criticisms psycho-analysis is regarded as 'inimical to culture' and has been put under a ban as a 'social danger'. This resistance cannot last for ever. No human institution can in the long run escape the influence of fair criticism; but men's attitude to psycho-analysis is still dominated by this fear, which gives rein to their passions and diminishes their power of logical argument.

By its theory of the instincts psycho-analysis offended the feelings of individuals in so far as they regarded themselves as members of the social community; another branch of its theory was calculated to hurt every single person at the tenderest point of his own psychical development. Psycho-analysis disposed once and for all of the fairy tale of an asexual childhood. It demonstrated the fact that sexual interests and activities occur in small children from the beginning of their lives. It showed what transformations those activities pass through, how at about the age of five they succumb to inhibition and how from puberty onwards they enter the service of the reproductive function. It recognized that early infantile sexual life reaches its peak in what is known as the Oedipus complex (an emotional attachment of the child to the parent of the opposite sex accompanied by an attitude of rivalry to the parent of the same sex) and that at that period of life this impulse extends uninhibited into a straightforward sexual desire. This can be confirmed so easily that only the greatest efforts could make it possible to overlook it. Every individual has in fact gone through this phase but has afterwards energetically repressed its purport and succeeded in forgetting it. A horror of incest and an enormous sense of guilt are left over from this prehistoric epoch of the individual's existence. It may be that something quite similar occurred in the prehistoric epoch of the human species as a whole and that the beginnings of morality, religion and social order were intimately connected with the surmounting of that *primaeva* era. To adults their prehistory seems so inglorious that they refuse to allow themselves to be reminded of it: they were infuriated when psycho-analysis tried to lift the veil of amnesia from their years of childhood. There was only one way out: what psycho-analysis asserted must be false and what posed as a new science must be a tissue of fancies and distortions.

Thus the strongest resistances to psycho-analysis were not of an intellectual kind but arose from emotional sources. This explained their passionate character as well as their poverty in logic. The situation obeyed a simple formula: men in the mass behaved to psycho-analysis in precisely the same way as individual neurotics under treatment for their disorders. It is possible, however, by patient work to convince these latter individuals that everything happened as we maintained it did: we had not invented it ourselves but had arrived at it from a study of other neurotics covering a period of twenty or thirty years. The position was at once alarming and consoling: alarming because it was no small thing to have the whole human race as one's patient, and consoling because after all everything was taking place as the hypotheses of psycho-analysis declared that it was bound to.

If we cast our eyes once again over the various resistances to psycho-analysis that have been enumerated, it is evident that only a minority of them are of the kind which habitually arise against most scientific innovations of any considerable importance. The majority of them are due to the fact that powerful human feelings are hurt by the subject-matter of the theory. Darwin's theory of descent met with the same fate, since it tore down the barrier that had been arrogantly set up between men and beasts. I drew attention to this analogy in an earlier paper,¹ in which I showed how the psycho-analytic view of the relation of the conscious ego to an overpowering unconscious was a severe blow to human self-love. I described this as the *psychological* blow to men's narcissism, and compared it with the *biological* blow delivered by the theory of descent and the earlier *cosmological* blow aimed at it by the discovery of Copernicus.

¹ 'A Difficulty in the Path of Psycho-Analysis' (1917a).

Purely external difficulties have also contributed to strengthen the resistance to psycho-analysis. It is not easy to arrive at an independent judgement upon matters to do with analysis without having experienced it oneself or practised it on someone else. Nor can one do the latter without having acquired a specific and decidedly delicate technique, while until recently there was no easily accessible means of learning psycho-analysis and its technique. This position has now been improved by the foundation (in 1920) of the Berlin Psycho-Analytic Clinic and Training Institute, and soon afterwards (in 1922) of an exactly similar institute in Vienna.

Finally, with all reserve, the question may be raised whether the personality of the present writer as a Jew who has never sought to disguise the fact that he is a Jew may not have had a share in provoking the antipathy of his environment to psycho-analysis. An argument of this kind is not often uttered aloud. But we have unfortunately grown so suspicious that we cannot avoid thinking that this factor may not have been quite without its effect. Nor is it perhaps entirely a matter of chance that the first advocate of psycho-analysis was a Jew. To profess belief in this new theory called for a certain degree of readiness to accept a situation of solitary opposition - a situation with which no one is more familiar than a Jew.

A NOTE UPON THE 'MYSTIC WRITING-PAD'
(1925)

Intentionally left blank

A NOTE UPON THE 'MYSTIC WRITING-PAD'

If I distrust my memory - neurotics, as we know, do so to a remarkable extent, but normal people have every reason for doing so as well - I am able to supplement and guarantee its working by making a note in writing. In that case the surface upon which this note is preserved, the pocket-book or sheet of paper, is as it were a materialized portion of my mnemonic apparatus, which I otherwise carry about with me invisible. I have only to bear in mind the place where this 'memory' has been deposited and I can then 'reproduce' it at any time I like, with the certainty that it will have remained unaltered and so have escaped the possible distortions to which it might have been subjected in my actual memory.

If I want to make full use of this technique for improving my mnemonic function, I find that there are two different procedures open to me. On the one hand, I can choose a writing-surface which will preserve intact any note made upon it for an indefinite length of time - for instance, a sheet of paper which I can write upon in ink. I am then in possession of a 'permanent memory-trace'. The disadvantage of this procedure is that the receptive capacity of the writing-surface is soon exhausted. The sheet is filled with writing, there is no room on it for any more notes, and I find myself obliged to bring another sheet into use, that has not been written on. Moreover, the advantage of this procedure, the fact that it provides a 'permanent trace', may lose its value for me if after a time the note ceases to interest me and I no longer want to 'retain it in my memory'. The alternative procedure avoids both of these disadvantages. If, for instance, I write with a piece of chalk on a slate, I have a receptive surface which retains its receptive capacity for an unlimited time and the notes upon which can be destroyed as soon as they cease to interest me, without any need for throwing away the writing-surface itself. Here the disadvantage is that I cannot preserve a permanent trace. If I want to put some fresh notes on the slate, I must first wipe out the ones which cover it. Thus an unlimited receptive capacity and a retention of permanent traces seem to be mutually exclusive properties in the apparatus which we use as substitutes for our memory: either the receptive surface must be renewed or the note must be destroyed.

All the forms of auxiliary apparatus which we have invented for the improvement or intensification of our sensory functions are built on the same model as the sense organs themselves or portions of them: for instance, spectacles, photographic cameras, ear-trumpets. Measured by this standard, devices to aid our memory seem particularly imperfect, since our mental apparatus accomplishes precisely what they cannot: it has an unlimited receptive capacity for new perceptions and nevertheless lays down permanent - even though not unalterable - memory-traces of them. As long ago as in 1900 I gave expression in *The Interpretation of Dreams* to a suspicion that this unusual capacity was to be divided between two different systems (or organs of the mental apparatus). According to this view, we possess a system *Pcpt.-Cs.*, which receives perceptions but retains no permanent trace of them, so that it can react like a clean sheet to every new perception; while the permanent traces of the excitations which have been received are preserved in 'mnemic systems' lying behind the perceptual system. Later, in *Beyond the Pleasure Principle* (1920g), I added a remark to the effect that the inexplicable phenomenon of consciousness arises in the perceptual system *instead of* the permanent traces.

Now some time ago there came upon the market, under the name of the 'Mystic Writing-Pad', a small contrivance that promises to perform more than the sheet of paper or the slate. It claims to be nothing more than a writing-tablet from which notes can be erased by an easy movement of the hand. But if it is examined more closely it will be found that its construction shows a remarkable agreement with my hypothetical structure of our perceptual apparatus and that it can in fact provide both an ever-ready receptive surface and permanent traces of the notes that have been made upon it.

The Mystic Pad is a slab of dark brown resin or wax with a paper edging; over the slab is laid a thin transparent sheet, the top end of which is firmly secured to the slab while its bottom end rests on it without being fixed to it. This transparent sheet is the more interesting part of the little device. It itself consists of two layers, which can be detached from each other except at their two ends. The upper layer is a transparent piece of celluloid; the lower layer is made of thin translucent waxed paper. When the apparatus is not in use, the lower surface of the waxed paper adheres lightly to the upper surface of the wax slab.

To make use of the Mystic Pad, one writes upon the celluloid portion of the covering-sheet which rests on the wax slab. For this purpose no pencil or chalk is necessary, since the writing does not depend on material being deposited on the receptive surface. It is a return to the ancient method of writing on tablets of clay or wax: a pointed stilus scratches the surface, the depressions upon which constitute the 'writing'. In the case of the Mystic Pad this scratching is not effected directly, but through the medium of the covering-sheet. At the points which the stilus touches, it presses the lower surface of the waxed paper on to the wax slab, and the grooves are visible as dark writing upon the otherwise smooth whitish-grey surface of the celluloid. If one wishes to destroy what has been written, all that is necessary is to raise the double covering-sheet from the wax slab by a light pull, starting from the free lower end. The close contact between the waxed paper and the wax slab at the places which have been scratched (upon which the visibility of the writing depended) is thus brought to an end and it does not recur when the two surfaces come together once more. The Mystic Pad is now clear of writing and ready to receive fresh notes.

The small imperfections of the contrivance have, of course, no importance for us, since we are only concerned with its approximation to the structure of the perceptual apparatus of the mind.

If, while the Mystic Pad has writing on it, we cautiously raise the celluloid from the waxed paper, we can see the writing just as clearly on the surface of the latter, and the question may arise why there should be any necessity for the celluloid portion of the cover. Experiment will then show that the thin paper would be very easily crumpled or torn if one were to write directly upon it with the stilus. The layer of celluloid thus acts as a protective sheath for the waxed paper, to keep off injurious effects from without. The celluloid is a 'protective shield against stimuli'; the layer which actually receives the stimuli is the paper. I may at this point recall that in *Beyond the Pleasure Principle* I showed that the perceptual apparatus of our mind consists of two layers, of an external protective shield against stimuli whose task it is to diminish the strength of excitations coming in, and of a surface behind it which receives the stimuli, namely the system *Pcpt.-Cs.*

The analogy would not be of much value if it could not be pursued further than this. If we lift the entire covering-sheet - both the celluloid and the waxed paper - off the wax slab, the writing vanishes and, as I have already remarked, does not re-appear again. The surface of the Mystic Pad is clear of writing and once more capable of receiving impressions. But it is easy to discover that the permanent trace of what was written is retained upon the wax slab itself and is legible in suitable lights. Thus the Pad provides not only a receptive surface that can be used over and over again, like a slate, but also permanent traces of what has been written, like an ordinary paper pad: it solves the problem of combining the two functions *by dividing them between two separate but interrelated component parts or systems*. But this is precisely the way in which, according to the hypothesis which I mentioned just now, our mental apparatus performs its perceptual function. The layer which receives the stimuli - the system *Pcpt.-Cs.* - forms no permanent traces; the foundations of memory come about in other, adjoining, systems.

We need not be disturbed by the fact that in the Mystic Pad no use is made of the permanent traces of the notes that have been received; it is enough that they are present. There must come a point at which the analogy between an auxiliary apparatus of this kind and the organ which is its prototype will cease to apply. It is true, too, that once the writing has been erased, the Mystic Pad cannot 'reproduce' it from within; it would be a mystic pad indeed if, like our memory, it could accomplish that. None the less, I do not think it is too far-fetched to compare the celluloid and waxed paper cover with the system *Pcpt.-Cs.* and its protective shield, the wax slab with the unconscious behind them, and the appearance and disappearance of the writing with the flickering-up and passing-away of consciousness in the process of perception.

But I must admit that I am inclined to press the comparison still further. On the Mystic Pad the writing vanishes every time the close contact is broken between the paper which receives the stimulus and the wax slab which preserves the impression. This agrees with a notion which I have long had about the method by which the perceptual apparatus of our mind functions, but which I have hitherto kept to myself. My theory was that cathectic innervations are sent out and withdrawn in rapid periodic impulses from within into the completely pervious system *Pcpt.-Cs.* So long as that system is cathected in this manner, it receives perceptions (which are accompanied by consciousness) and passes the excitation on to the unconscious mnemonic systems; but as soon as the cathexis is withdrawn, consciousness is extinguished and the functioning of the system comes to a standstill. It is as though the unconscious stretches out feelers, through the medium of the system *Pcpt.-Cs.*, towards the external world and hastily withdraws them as soon as they have sampled the excitations coming from it. Thus the interruptions, which in the case of the Mystic Pad have an external origin, were attributed by my hypothesis to the discontinuity in the current of innervation; and the actual breaking of contact which occurs in the Mystic Pad was replaced in my theory by the periodic non-excitability of the perceptual system. I further had a suspicion that this discontinuous method of functioning of the system *Pcpt.-Cs.* lies at the bottom of the origin of the concept of time.

If we imagine one hand writing upon the surface of the Mystic Writing-Pad while another periodically raises its covering-sheet from the wax slab, we shall have a concrete representation of the way in which I tried to picture the functioning of the perceptual apparatus of our mind.

NEGATION
(1925)

Intentionally left blank

NEGATION

The manner in which our patients bring forward their associations during the work of analysis gives us an opportunity for making some interesting observations. 'Now you'll think I mean to say something insulting, but really I've no such intention.' we realize that this is a rejection, by projection, of an idea that has just come up. Or: 'You ask who this person in the dream can be. It's *not* my mother.' We emend this to: 'So it *is* his mother.' In our interpretation, we take the liberty of disregarding the negation and of picking out the subject-matter alone of the association. It is as though the patient had said: 'It's true that my mother came into my mind as I thought of this person, but I don't feel inclined to let the association count.'

There is a very convenient method by which we can sometimes obtain a piece of information we want about unconscious repressed material. 'What', we ask, 'would you consider the most unlikely imaginable thing in that situation? What do you think was furthest from your mind at that time?' If the patient falls into the trap and says what he thinks is most incredible, he almost always makes the right admission. A neat counterpart to this experiment is often met with in an obsessional neurotic who has already been initiated into the meaning of his symptoms. 'I've got a new obsessive idea,' he says, 'and it occurred to me at once that it might mean so and so. But no; that can't be true, or it couldn't have occurred to me.' What he is repudiating, on grounds picked up from his treatment, is, of course, the correct meaning of the obsessive idea.

Thus the content of a repressed image or idea can make its way into consciousness, on condition that it is *negated*. Negation is a way of taking cognizance of what is repressed; indeed it is already a lifting of the repression, though not, of course, an acceptance of what is repressed. We can see how in this the intellectual function is separated from the affective process. With the help of negation only one consequence of the process of repression is undone - the fact, namely, of the ideational content of what is repressed not reaching consciousness. The outcome of this is a kind of intellectual acceptance of the repressed, while at the same time what is essential to the repression persists.¹ In the course of analytic work we often produce a further, very important and somewhat strange variant of this situation. We succeed in conquering the negation as well, and in bringing about a full intellectual acceptance of the repressed; but the repressive process itself is not yet removed by this.

Since to affirm or negate the content of thoughts is the task of the function of intellectual judgement, what we have just been saying has led us to the psychological origin of that function. To negate something in a judgement is, at bottom, to say: 'This is something which I should prefer to repress.' A negative judgement is the intellectual substitute for repression; its 'no' is the hall-mark of repression, a certificate of origin like, let us say, 'Made in Germany'. With the help of the symbol of negation, thinking frees itself from the restrictions of repression and enriches itself with material that is indispensable for its proper functioning.

The function of judgement is concerned in the main with two sorts of decisions. It affirms or disaffirms the possession by a thing of a particular attribute; and it asserts or disputes that a presentation has an existence in reality. The attribute to be decided about may originally have been good or bad, useful or harmful. Expressed in the language of the oldest - the oral - instinctual impulses, the judgement is: 'I should like to eat this', or 'I should like to spit it out'; and, put more generally: 'I should like to take this into myself and to keep that out.' That is to say: 'It shall be inside me' or 'it shall be outside me'. As I have shown elsewhere, the original pleasure-ego wants to introject into itself everything that is good and to eject from itself everything that is bad. What is bad, what is alien to the ego and what is external are, to begin with, identical.²

¹ The same process is at the root of the familiar superstition that boasting is dangerous. 'How nice not to have had one of my headaches for so long.' But this is in fact the first announcement of an attack, of whose approach the subject is already sensible, although he is as yet unwilling to believe it.

² See the discussion in 'Instincts and their Vicissitudes' (1915c).

The other sort of decision made by the function of judgement - as to the real existence of something of which there is a presentation (reality-testing) - is a concern of the definitive reality-ego, which develops out of the initial pleasure-ego. It is now no longer a question of whether what has been perceived (a thing) shall be taken into the ego or not, but of whether something which is in the ego as a presentation can be rediscovered in perception (reality) as well. It is, we see, once more a question of *external* and *internal*. What is unreal, merely a presentation and subjective, is only internal; what is real is also there *outside*. In this stage of development regard for the pleasure principle has been set aside. Experience has shown the subject that it is not only important whether a thing (an object of satisfaction for him) possesses the 'good' attribute and so deserves to be taken into his ego, but also whether it is there in the external world, so that he can get hold of it whenever he needs it. In order to understand this step forward we must recollect that all presentations originate from perceptions and are repetitions of them. Thus originally the mere existence of a presentation was a guarantee of the reality of what was presented. The antithesis between subjective and objective does not exist from the first. It only comes into being from the fact that thinking possesses the capacity to bring before the mind once more something that has once been perceived, by reproducing it as a presentation without the external object having still to be there. The first and immediate aim, therefore, of reality-testing is, not to *find* an object in real perception which corresponds to the one presented, but to *refind* such an object, to convince oneself that it is still there. Another capacity of the power of thinking offers a further contribution to the differentiation between what is subjective and what is objective. The reproduction of a perception as a presentation is not always a faithful one; it may be modified by omissions, or changed by the merging of various elements. In that case, reality-testing has to ascertain how far such distortions go. But it is evident that a precondition for the setting up of reality-testing is that objects shall have been lost which once brought real satisfaction.

Judging is the intellectual action which decides the choice of motor action, which puts an end to the postponement due to thought and which leads over from thinking to acting. This postponement due to thought has also been discussed by me elsewhere. It is to be regarded as an experimental action, a motor palpating, with small expenditure of discharge. Let us consider where the ego has used a similar kind of palpating before, at what place it learnt the technique which it now applies in its processes of thought. It happened at the sensory end of the mental apparatus, in connection with sense perceptions. For, on our hypothesis, perception is not a purely passive process. The ego periodically sends out small amounts of cathexis into the perceptual system, by means of which it samples the external stimuli, and then after every such tentative advance it draws back again.

The study of judgement affords us, perhaps for the first time, an insight into the origin of an intellectual function from the interplay of the primary instinctual impulses. Judging is a continuation, along lines of expediency, of the original process by which the ego took things into itself or expelled them from itself, according to the pleasure principle. The polarity of judgement appears to correspond to the opposition of the two groups of instincts which we have supposed to exist. Affirmation - as a substitute for uniting - belongs to Eros; negation - the successor to expulsion - belongs to the instinct of destruction. The general wish to negate, the negativism which is displayed by some psychotics, is probably to be regarded as a sign of a defusion of instincts that has taken place through a withdrawal of the libidinal components. But the performance of the function of judgement is not made possible until the creation of the symbol of negation has endowed thinking with a first measure of freedom from the consequences of repression and, with it, from the compulsion of the pleasure principle.

This view of negation fits in very well with the fact that in analysis we never discover a 'no' in the unconscious and that recognition of the unconscious on the part of the ego is expressed in a negative formula. There is no stronger evidence that we have been successful in our effort to uncover the unconscious than when the patient reacts to it with the words 'I didn't think that', or 'I didn't (ever) think of that'.

SOME PSYCHICAL CONSEQUENCES OF THE ANATOMICAL DISTINCTION
BETWEEN THE SEXES
(1925)

Intentionally left blank

SOME PSYCHICAL CONSEQUENCES OF THE ANATOMICAL DISTINCTION BETWEEN THE SEXES

In my own writings and in those of my followers more and more stress is laid on the necessity that the analyses of neurotics shall deal thoroughly with the remotest period of their childhood, the time of the early efflorescence of sexual life. It is only by examining the first manifestations of the patient's innate instinctual constitution and the effects of his earliest experiences that we can accurately gauge the motive forces that have led to his neurosis and can be secure against the errors into which we might be tempted by the degree to which things have become remodelled and overlaid in adult life. This requirement is not only of theoretical but also of practical importance, for it distinguishes our efforts from the work of those physicians whose interests are focused exclusively on therapeutic results and who employ analytic methods, but only up to a certain point. An analysis of early childhood such as we are considering is tedious and laborious and makes demands both upon the physician and upon the patient which cannot always be met. Moreover, it leads us into dark regions where there are as yet no sign posts. Indeed, analysts may feel reassured, I think, that there is no risk of their work becoming mechanical, and so of losing its interest, during the next few decades.

In the following pages I bring forward some findings of analytic research which would be of great importance if they could be proved to apply universally. Why do I not postpone publication of them until further experience has given me the necessary proof, if such proof is obtainable? Because the conditions under which I work have undergone a change, with implications which I cannot disguise. Formerly, I was not one of those who are unable to hold back what seems to be a new discovery until it has been either confirmed or corrected. My *Interpretation of Dreams* (1900a) and my 'Fragment of an Analysis of a Case of Hysteria' (1905e) (the case of Dora) were suppressed by me - if not for the nine years enjoined by Horace - at all events for four or five years before I allowed them to be published. But in those days I had unlimited time before me - 'oceans of time' as an amiable author puts it - and material poured in upon me in such quantities that fresh experiences were hardly to be escaped. Moreover, I was the only worker in a new field, so that my reticence involved no danger to myself and no loss to others.

But now everything has changed. The time before me is limited. The whole of it is no longer spent in working, so that my opportunities for making fresh observations are not so numerous. If I think I see something new, I am uncertain whether I can wait for it to be confirmed. And further, everything that is to be seen upon the surface has already been exhausted; what remains has to be slowly and laboriously dragged up from the depths. Finally, I am no longer alone. An eager crowd of fellow-workers is ready to make use of what is unfinished or doubtful, and I can leave to them that part of the work which I should otherwise have done myself. On this occasion, therefore, I feel justified in publishing something which stands in urgent need of confirmation before its value or lack of value can be decided.

In examining the earliest mental shapes assumed by the sexual life of children we have been in the habit of taking as the subject of our investigations the male child, the little boy. With little girls, so we have supposed, things must be similar, though in some way or other they must nevertheless be different. The point in development at which this difference lay could not be clearly determined.

In boys the situation of the Oedipus complex is the first stage that can be recognized with certainty. It is easy to understand, because at that stage a child retains the same object which he previously cathected with his libido - not as yet a genital one - during the preceding period while he was being suckled and nursed. The fact, too, that in this situation he regards his father as a disturbing rival and would like to get rid of him and take his place is a straightforward consequence of the actual state of affairs. I have shown elsewhere¹ how the Oedipus attitude in little boys belongs to the phallic phase, and how its destruction is brought about by the fear of castration - that is, by narcissistic interest in their genitals. The matter is made more difficult to grasp by the complicating circumstance that even in boys the Oedipus complex has a double orientation, active and passive, in accordance with their bisexual constitution; a boy also wants to take his *mother's* place as the love-object of his *father* - a fact which we describe as the feminine attitude.

¹ 'The Dissolution of the Oedipus Complex' (1924*d*).

As regards the prehistory of the Oedipus complex in boys we are far from complete clarity. We know that that period includes an identification of an affectionate sort with the boy's father, an identification which is still free from any sense of rivalry in regard to his mother. Another element of that stage is invariably, I believe, a masturbatory activity in connection with the genitals, the masturbation of early childhood, the more or less violent suppression of which by those in charge of the child sets the castration complex in action. It is to be assumed that this masturbation is attached to the Oedipus complex and serves as a discharge for the sexual excitation belonging to it. It is, however, uncertain whether the masturbation has this character from the first, or whether on the contrary it makes its first appearance spontaneously as an activity of a bodily organ and is only brought into relation with the Oedipus complex at some later date; this second possibility is by far the more probable. Another doubtful question is the part played by bed-wetting and by the breaking of that habit through the intervention of training measures. We are inclined to make the simple connection that continued bed-wetting is a result of masturbation and that its suppression is regarded by boys as an inhibition of their genital activity - that is, as having the meaning of a threat of castration; but whether we are always right in supposing this remains to be seen. Finally, analysis shows us in a shadowy way how the fact of a child at a very early age listening to his parents copulating may set up his first sexual excitation, and how that event may, owing to its after-effects, act as a starting-point for the child's whole sexual development. Masturbation, as well as the two attitudes in the Oedipus complex, later on become attached to this early experience, the child having subsequently interpreted its meaning. It is impossible, however, to suppose that these observations of coitus are of universal occurrence, so that at this point we are faced with the problem of 'primal phantasies'. Thus the prehistory of the Oedipus complex, even in boys, raises all of these questions for sifting and explanation; and there is the further problem of whether we are to suppose that the process invariably follows the same course, or whether a great variety of different preliminary stages may not converge upon the same terminal situation.

In little girls the Oedipus complex raises one problem more than in boys. In both cases the mother is the original object; and there is no cause for surprise that boys retain that object in the Oedipus complex. But how does it happen that girls abandon it and instead take their father as an object? In pursuing this question I have been able to reach some conclusions which may throw light precisely on the prehistory of the Oedipus relation in girls.

Every analyst has come across certain women who cling with especial intensity and tenacity to the bond with their father and to the wish in which it culminates of having a child by him. We have good reason to suppose that the same wishful phantasy was also the motive force of their infantile masturbation, and it is easy to form an impression that at this point we have been brought up against an elementary and unanalysable fact of infantile sexual life. But a thorough analysis of these very cases brings something different to light - namely, that here the Oedipus complex has a long prehistory and is in some respects a secondary formation.

The old paediatrician Lindner once remarked that a child discovers the genital zones (the penis or the clitoris) as a source of pleasure while indulging in sensual sucking (thumb sucking).¹ I shall leave it an open question whether it is really true that the child takes the newly found source of pleasure in exchange for the recent loss of the mother's nipple - a possibility to which later phantasies (fellatio) seem to point. Be that as it may, the genital zone is discovered at some time or other, and there seems no justification for attributing any psychical content to the first activities in connection with it. But the first step in the phallic phase which begins in this way is not the linking-up of the masturbation with the object-cathexes of the Oedipus complex, but a momentous discovery which little girls are destined to make. They notice the penis of a brother or playmate, strikingly visible and of large proportions, at once recognize it as the superior counterpart of their own small and inconspicuous organ, and from that time forward fall a victim to envy for the penis.

¹ Cf. *Three Essays on the Theory of Sexuality* (1905d).

There is an interesting contrast between the behaviour of the two sexes. In the analogous situation, when a little boy first catches sight of a girl's genital region, he begins by showing irresolution and lack of interest; he sees nothing or disavows what he has seen, he softens it down or looks about for expedients for bringing it into line with his expectations. It is not until later, when some threat of castration has obtained a hold upon him, that the observation becomes important to him: if he then recollects or repeats it, it arouses a terrible storm of emotion in him and forces him to believe in the reality of the threat which he has hitherto laughed at. This combination of circumstances leads to two reactions, which may become fixed and will in that case, whether separately or together or in conjunction with other factors, permanently determine the boy's relations to women: horror of the mutilated creature or triumph and contempt for her. These developments, however, belong to the future, though not to a very remote one.

A little girl behaves differently. She makes her judgement and her decision in a flash. She has seen it and knows that she is without it and wants to have it.¹

¹ This is an opportunity for correcting a statement which I made many years ago. I believed that the sexual interest of children, unlike that of pubescents, was aroused, not by the difference between the sexes, but by the problem of where babies come from. We now see that, at all events with girls, this is certainly not the case. With boys it may no doubt happen sometimes one way and sometimes the other; or with both sexes chance experiences may determine the event.

Here what has been named the masculinity complex of women branches off. It may put great difficulties in the way of their regular development towards femininity, if it cannot be got over soon enough. The hope of some day obtaining a penis in spite of everything and so of becoming like a man may persist to an incredibly late age and may become a motive for strange and otherwise unaccountable actions. Or again, a process may set in which I should like to call a 'disavowal', a process which in the mental life of children seems neither uncommon nor very dangerous but which in an adult would mean the beginning of a psychosis. Thus a girl may refuse to accept the fact of being castrated, may harden herself in the conviction that she *does* possess a penis, and may subsequently be compelled to behave as though she were a man.

The psychical consequences of envy for the penis, in so far as it does not become absorbed in the reaction-formation of the masculinity complex, are various and far-reaching. After a woman has become aware of the wound to her narcissism, she develops, like a scar, a sense of inferiority. When she has passed beyond her first attempt at explaining her lack of a penis as being a punishment personal to herself and has realized that that sexual character is a universal one, she begins to share the contempt felt by men for a sex which is the lesser in so important a respect, and, at least in holding that opinion, insists on being like a man.¹

¹ In my first critical account of the 'History of the Psycho-Analytic Movement' (1914*d*), I recognized that this fact represents the core of truth contained in Adler's theory. That theory has no hesitation in explaining the whole world by this single point ('organ inferiority', the 'masculine protest', 'breaking away from the feminine line') and prides itself upon having in this way robbed sexuality of its importance and put the desire for power in its place! Thus the only organ which could claim to be called 'inferior' without any ambiguity would be the clitoris. On the other hand, one hears of analysts who boast that, though they have worked for dozens of years, they have never found a sign of the existence of a castration complex. We must bow our heads in recognition of the greatness of this achievement, even though it is only a negative one, a piece of virtuosity in the art of overlooking and mistaking. The two theories form an interesting pair of opposites: in the latter not a trace of a castration complex, in the former nothing else than its consequences.

Even after penis-envy has abandoned its true object, it continues to exist: by an easy displacement it persists in the character-trait of *jealousy*. Of course, jealousy is not limited to one sex and has a wider foundation than this, but I am of opinion that it plays a far larger part in the mental life of women than of men and that that is because it is enormously reinforced from the direction of displaced penis-envy. While I was still unaware of this source of jealousy and was considering the phantasy 'a child is being beaten', which occurs so commonly in girls, I constructed a first phase for it in which its meaning was that another child, a rival of whom the subject was jealous, was to be beaten.¹ This phantasy seems to be a relic of the phallic period in girls. The peculiar rigidity which struck me so much in the monotonous formula 'a child is being beaten' can probably be interpreted in a special way. The child which is being beaten (or caressed) may ultimately be nothing more nor less than the clitoris itself, so that at its very lowest level the statement will contain a confession of masturbation, which has remained attached to the content of the formula from its beginning in the phallic phase till later life.

A third consequence of penis-envy seems to be a loosening of the girl's relation with her mother as a love-object. The situation as a whole is not very clear, but it can be seen that in the end the girl's mother, who sent her into the world so insufficiently equipped, is almost always held responsible for her lack of a penis. The way in which this comes about historically is often that soon after the girl has discovered that her genitals are unsatisfactory she begins to show jealousy of another child on the ground that her mother is fonder of it than of her, which serves as a reason for her giving up her affectionate relation to her mother. It will fit in with this if the child which has been preferred by her mother is made into the first object of the beating-phantasy which ends in masturbation.

¹ "'A child is Being Beaten'" (1919e).

There is yet another surprising effect of penis-envy, or of the discovery of the inferiority of the clitoris, which is undoubtedly the most important of all. In the past I had often formed an impression that in general women tolerate masturbation worse than men, that they more frequently fight against it and that they are unable to make use of it in circumstances in which a man would seize upon it as a way of escape without any hesitation. Experience would no doubt elicit innumerable exceptions to this statement, if we attempted to turn it into a rule. The reactions of human individuals of both sexes are of course made up of masculine and feminine traits. But it appeared to me nevertheless as though masturbation were further removed from the nature of women than of men, and the solution of the problem could be assisted by the reflection that masturbation, at all events of the clitoris, is a masculine activity and that the elimination of clitoridal sexuality is a necessary precondition for the development of femininity. Analyses of the remote phallic period have now taught me that in girls, soon after the first signs of penis-envy, an intense current of feeling against masturbation makes its appearance, which cannot be attributed exclusively to the educational influence of those in charge of the child. This impulse is clearly a forerunner of the wave of repression which at puberty will do away with a large amount of the girl's masculine sexuality in order to make room for the development of her femininity. It may happen that this first opposition to auto-erotic activity fails to attain its end. And this was in fact the case in the instances which I analysed. The conflict continued, and both then and later the girl did everything she could to free herself from the compulsion to masturbate. Many of the later manifestations of sexual life in women remain unintelligible unless this powerful motive is recognized.

I cannot explain the opposition which is raised in this way by little girls to phallic masturbation except by supposing that there is some concurrent factor which turns her violently against that pleasurable activity. Such a factor lies close at hand. It cannot be anything else than her narcissistic sense of humiliation which is bound up with penis-envy, the reminder that after all this is a point on which she cannot compete with boys and that it would therefore be best for her to give up the idea of doing so. Thus the little girl's recognition of the anatomical distinction between the sexes forces her away from masculinity and masculine masturbation on to new lines which lead to the development of femininity.

So far there has been no question of the Oedipus complex, nor has it up to this point played any part. But now the girl's libido slips into a new position along the line - there is no other way of putting it - of the equation 'penis-child'. She gives up her wish for a penis and puts in place of it a wish for a child: and *with that purpose in view* she takes her father as a love object. Her mother becomes the object of her jealousy. The girl has turned into a little woman. If I am to credit a single analytic instance, this new situation can give rise to physical sensations which would have to be regarded as a premature awakening of the female genital apparatus. When the girl's attachment to her father comes to grief later on and has to be abandoned, it may give place to an identification with him and the girl may thus return to her masculinity complex and perhaps remain fixated in it.

I have now said the essence of what I had to say: I will stop, therefore, and cast an eye over our findings. We have gained some insight into the prehistory of the Oedipus complex in girls. The corresponding period in boys is more or less unknown. In girls the Oedipus complex is a secondary formation. The operations of the castration complex precede it and prepare for it. As regards the relation between the Oedipus and castration complexes there is a fundamental contrast between the two sexes. *Whereas in boys the Oedipus complex is destroyed by the castration complex, in girls it is made possible and led up to by the castration complex.* This contradiction is cleared up if we reflect that the castration complex always operates in the sense implied in its subject-matter: it inhibits and limits masculinity and encourages femininity. The difference between the sexual development of males and females at the stage we have been considering is an intelligible consequence of the anatomical distinction between their genitals and of the psychical situation involved in it; it corresponds to the difference between a castration that has been carried out and one that has merely been threatened. In their essentials, therefore, our findings are self-evident and it should have been possible to foresee them.

The Oedipus complex, however, is such an important thing that the manner in which one enters and leaves it cannot be without its effects. In boys (as I have shown at length in the paper to which I have just referred and to which all of my present remarks are closely related) the complex is not simply repressed, it is literally smashed to pieces by the shock of threatened castration. Its libidinal cathexes are abandoned, desexualized and in part sublimated; its objects are incorporated into the ego, where they form the nucleus of the super-ego and give that new structure its characteristic qualities. In normal, or, it is better to say, in ideal cases, the Oedipus complex exists no longer, even in the unconscious; the super-ego has become its heir. Since the penis (to follow Ferenczi) owes its extraordinarily high narcissistic cathexis to its organic significance for the propagation of the species, the catastrophe to the Oedipus complex (the abandonment of incest and the institution of conscience and morality) may be regarded as a victory of the race over the individual. This is an interesting point of view when one considers that neurosis is based upon a struggle of the ego against the demands of the sexual function. But to leave the standpoint of individual psychology is not of any immediate help in clarifying this complicated situation.

In girls the motive for the demolition of the Oedipus complex is lacking. Castration has already had its effect, which was to force the child into the situation of the Oedipus complex. Thus the Oedipus complex escapes the fate which it meets with in boys: it may be slowly abandoned or dealt with by repression, or its effects may persist far into women's normal mental life. I cannot evade the notion (though I hesitate to give it expression) that for women the level of what is ethically normal is different from what it is in men. Their super-ego is never so inexorable, so impersonal, so independent of its emotional origins as we require it to be in men. Character-traits which critics of every epoch have brought up against women - that they show less sense of justice than men, that they are less ready to submit to the great exigencies of life, that they are more often influenced in their judgements by feelings of affection or hostility - all these would be amply accounted for by the modification in the formation of their super-ego which we have inferred above. We must not allow ourselves to be deflected from such conclusions by the denials of the feminists, who are anxious to force us to regard the two sexes as completely equal in position and worth; but we shall, of course, willingly agree that the majority of men are also far behind the masculine ideal and that all human individuals, as a result of their bisexual disposition and of cross-inheritance, combine in themselves both masculine and feminine characteristics, so that pure masculinity and femininity remain theoretical constructions of uncertain content.

I am inclined to set some value on the considerations I have brought forward upon the psychical consequences of the anatomical distinction between the sexes. I am aware, however, that this opinion can only be maintained if my findings, which are based on a handful of cases, turn out to have general validity and to be typical. If not, they would remain no more than a contribution to our knowledge of the different paths along which sexual life develops.

In the valuable and comprehensive studies on the masculinity and castration complexes in women by Abraham (1921), Horney (1923) and Helene Deutsch (1925) there is much that touches closely on what I have written but nothing that coincides with it completely, so that here again I feel justified in publishing this paper.

JOSEF POPPER-LYNKEUS AND THE THEORY OF DREAMS
(1923)

Intentionally left blank

JOSEF POPPER-LYNKEUS AND THE THEORY OF DREAMS

There is much of interest to be said on the subject of apparent scientific originality. When some new idea comes up in science, which is hailed at first as a discovery and is also as a rule disputed as such, objective research soon afterwards reveals that after all it was in fact no novelty. Usually the discovery has already been made repeatedly and has afterwards been forgotten, often at very long intervals of time. Or at least it has had forerunners, had been obscurely surmised or incompletely enunciated. This is too well known to call for further discussion.

But the subjective side of originality also deserves consideration. A scientific worker may sometimes ask himself what was the source of the ideas peculiar to himself which he has applied to his material. As regards some of them he will discover without much reflection the hints from which they were derived, the statements made by other people which he has picked out and modified and whose implications he has elaborated. But as regards others of his ideas he can make no such acknowledgements; he can only suppose that these thoughts and lines of approach were generated - he cannot tell how - in his own mental activity, and it is on them that he bases his claim to originality.

Careful psychological investigation, however, diminishes this claim still further. It reveals hidden and long-forgotten sources which gave the stimulus to the apparently original ideas, and it replaces the ostensible new creation by a revival of something forgotten applied to fresh material. There is nothing to regret in this; we had no right to expect that what was 'original' could be untraceable and undetermined.

In my case, too, the originality of many of the new ideas employed by me in the interpretation of dreams and in psycho-analysis has evaporated in this way. I am ignorant of the source of only one of these ideas. It was no less than the key to my view of dreams and helped me to solve their riddles, so far as it has been possible to solve them hitherto. I started out from the strange, confused and senseless character of so many dreams, and hit upon the notion that dreams were bound to become like that because something was struggling for expression in them which was opposed by a resistance from other mental forces. In dreams hidden impulses were stirring which stood in contradiction to what might be called the dreamer's official ethical and aesthetic creed; the dreamer was thus ashamed of these impulses, turned away from them and refused to acknowledge them in day-time, and if during the night he could not withhold expression of some kind from them, he submitted them to a 'dream-distortion' which made the content of the dream appear confused and senseless. To the mental force in human beings which keeps watch on this internal contradiction and distorts the dream's primitive instinctual impulses in favour of conventional or of higher moral standards, I gave the name of 'dream-censorship'.

Precisely this essential part of my theory of dreams was, however, discovered by Popper-Lynkeus independently. I will ask the reader to compare the following quotation from a story called 'Träumen wie Wachen' in his *Phantasien eines Realisten* which was certainly written in ignorance of the theory of dreams which I published in 1900, just as I myself was then in ignorance of Lynkeus's *Phantasien*:

'About a man who has the remarkable attribute of never dreaming nonsense.

"This splendid gift of yours, for dreaming as though you were waking, is a consequence of your virtues, of your kindness, your sense of justice, and your love of truth; it is the moral serenity of your nature which makes me understand all about you."

"But when I think the matter over properly", replied the other, "I almost believe that everyone is made like me, and that no one at all ever dreams nonsense. Any dream which one can remember clearly enough to describe it afterwards - any dream, that is to say, which is not a fever-dream - must *always* make sense, and it cannot possibly be otherwise. For things that were mutually contradictory could not group themselves into a single whole. The fact that time and space are often thrown into confusion does not affect the true content of the dream, since no doubt neither of them are of significance for its real essence. We often do the same thing in waking life. Only think of fairy tales and of the many daring products of the imagination, which are full of meaning and of which only a man without intelligence could say: 'This is nonsense, for it is impossible.'"

"If only one always knew how to interpret dreams in the right way, as you have just done with mine!" said his friend.

"That is certainly no easy task; but with a little attention on the part of the dreamer himself it should no doubt always succeed. - You ask why it is that for the most part it does *not* succeed? In you other people there seems always to be something that lies concealed in your dreams, something unchaste in a special and higher sense, a certain secret quality in your being which it is hard to follow. And that is why your dreams so often seem to be without meaning or even to be nonsense. But in the deepest sense this is not in the least so; indeed, it cannot be so at all - for it is always the same man, whether he is awake or dreaming."

I believe that what enabled *me* to discover the cause of dream-distortion was my moral courage. In the case of Popper it was the purity, love of truth and moral serenity of his nature.

DR. SÁNDOR FERENCZI
(ON HIS 50th BIRTHDAY)
(1923)

Intentionally left blank

DR. SÁNDOR FERENCZI
(ON HIS 50th BIRTHDAY)

Not many years after its publication (in 1900), *The Interpretation of Dreams* fell into the hands of a young Budapest physician, who, although he was a neurologist, psychiatrist and expert in forensic medicine, was eagerly in search of new scientific knowledge. He did not get far in reading the book; very soon he had thrown it aside - whether out of boredom or disgust is not known. Soon afterwards, however, the call for fresh possibilities of work and discovery took him to Zurich, and thence he was led to Vienna to meet the author of the book that he had once contemptuously cast aside. This first visit was succeeded by a long, intimate and hitherto untroubled friendship, in the course of which he too made the journey to America in 1909 to lecture at Clark University at Worcester, Mass.

Such were the beginnings of Ferenczi, who has since himself become a master and teacher of psycho-analysis and who in the present year, 1923, completes alike the fiftieth anniversary of his birth and the first decade of his leadership of the Budapest Psycho-Analytical Society.

Ferenczi has repeatedly played a part, too, in the external affairs of psycho-analysis. His appearance at the Second Analytical Congress, at Nuremberg in 1910, will be remembered, where he proposed and helped to bring about the foundation of an International Psycho-Analytical Association as a means of defence against the contempt with which analysis was treated by official Medicine. At the Fifth Analytical Congress, at Budapest, in September, 1918, he was elected President of the Association. He appointed Anton von Freund as Secretary; and there is no doubt that the combined energy of the two men, together with Freund's generous schemes of endowment, would have made Budapest the analytic capital of Europe, had not political catastrophes and personal tragedy put a merciless end to these fair hopes. Freund fell ill and died in January, 1920. In view of Hungary's isolation from contact with the rest of the world, Ferenczi had resigned his position in October, 1919, and had transferred the Presidency of the International Association to Ernest Jones in London. For the duration of the Soviet Republic in Hungary Ferenczi had been allotted the functions of a University teacher, and his lectures had attracted crowded audiences. The Branch Society, which he had founded in 1913,¹ survived every storm and, under his guidance, became a centre of intense and productive work and was distinguished by an accumulation of abilities such as were exhibited in combination by no other Branch Society. Ferenczi, who, as a middle child in a large family, had to struggle with a powerful brother complex, had, under the influence of analysis, become an irreproachable elder brother, a kindly teacher and promoter of young talent.

¹ Its Inaugural General Meeting was held on May 19, 1913, with Ferenczi as President, Dr. Radó as Secretary, and Drs. Hollós, Ignotus and Lévy as members.

Ferenczi's analytic writings have become universally known and appreciated. It was not until 1922 that his *Popular Lectures on Psycho-Analysis* were published by our *Verlag* as Volume XIII of the 'Internationale Psychoanalytische Bibliothek'. These lectures, clear and formally perfect, sometimes most fascinatingly written, offer what is in fact the best 'Introduction to Psycho-Analysis' for those who are unfamiliar with it. There is still no collection of his purely technical medical writings, a number of which have been translated into English by Ernest Jones. The *Verlag* will fulfil this task as soon as more favourable times make it possible. Those of his books and papers which have appeared in Hungarian have passed through many editions and have made analysis familiar to educated circles in Hungary.

Ferenczi's scientific achievement is impressive above all from its many-sidedness. Besides well-chosen case histories and acutely observed clinical communications ('A Little Chanticleer', 'Transitory Symptom-Constructions during the Analysis', and shorter clinical works) we find exemplary critical writings such as those upon Jung's *Wandlungen und Symbole der Libido*, upon Régis and Hesnard's views on psycho-analysis, as well as effective polemical writings such as those against Bleuler on alcohol and against Putnam on the relation between psycho-analysis and philosophy, moderate and dignified in spite of their decisiveness. But besides all these there are the papers upon which Ferenczi's fame principally rests, in which his originality, his wealth of ideas and his command over a well-directed scientific imagination find such happy expression, and with which he has enlarged important sections of psycho-analytic theory and has promoted the discovery of fundamental situations in mental life: 'Introjection and Transference', including a discussion of the theory of hypnosis, 'Stages in the Development of the Sense of Reality' and his discussion of symbolism. Finally there are the works of these last few years - 'The Psycho-Analysis of the War Neuroses', *Hysterie und Pathoneurosen* and, in collaboration with Hollós, *Psycho-Analysis and the Psychic Disorder of General Paresis* (in which the medical interest advances from the psychological conditions to the somatic determinants), and his approaches to an 'active' therapy.

However incomplete this enumeration may seem to be, his friends know that Ferenczi has held back even more than he has been able to make up his mind to communicate. On his fiftieth birthday they are united in wishing that he may be granted strength, leisure and a frame of mind to bring his scientific plans to realization in fresh achievements.

PREFACE TO AICHHORN'S *WAYWARD YOUTH*
(1925)

Intentionally left blank

PREFACE TO AICHHORN'S *WAYWARD YOUTH*

None of the applications of psycho-analysis has excited so much interest and aroused so many hopes, and none, consequently, has attracted so many capable workers, as its use in the theory and practice of education. It is easy to understand why; for children have become the main subject of psycho-analytic research and have thus replaced in importance the neurotics on whom its studies began. Analysis has shown how the child lives on, almost unchanged, in the sick man as well as in the dreamer and the artist; it has thrown light on the motive forces and trends which set its characteristic stamp upon the childish nature; and it has traced the stages through which a child grows to maturity. No wonder, therefore, if an expectation has arisen that psycho-analytic concern with children will benefit the work of education, whose aim it is to guide and assist children on their forward path and to shield them from going astray.

My personal share in this application of psycho-analysis been very slight. At an early stage I had accepted the from *bon mot* which lays it down that there are three impossible professions - educating, healing and governing - and I was already fully occupied with the second of them. But this does not mean that I overlook the high social value of the work done by those of my friends who are engaged in education.

The present volume by August Aichhorn is concerned with one department of the great problem - with the educational influencing of juvenile delinquents. The author had worked for many years in an official capacity as a director of municipal institutions for delinquents before he became acquainted with psycho-analysis. His attitude to his charges sprang from a warm sympathy with the fate of those unfortunates and was correctly guided by an intuitive perception of their mental needs. Psycho-analysis could teach him little that was new of a practical kind, but it brought him a clear theoretical insight into the justification of his way of acting and put him in a position to explain its basis to other people.

It must not be assumed that this gift of intuitive understanding will be found in everyone concerned with the bringing-up of children. Two lessons may be derived, it seems to me, from the experience and the success of August Aichhorn. One is that every such person should receive a psycho-analytic training, since without it children, the object of his endeavours, must remain an inaccessible problem to him. A training of this kind is best carried out if such a person himself undergoes an analysis and experiences it on himself: theoretical instruction in analysis fails to penetrate deep enough and carries no conviction.

The second lesson has a somewhat conservative ring. It is to the effect that the work of education is something *sui generis*: it is not to be confused with psycho-analytic influence and cannot be replaced by it. Psycho-analysis can be called in by education as an auxiliary means of dealing with a child; but it is not a suitable substitute for education. Not only is such a substitution impossible on practical grounds but it is also to be disrecommended for theoretical reasons. The relation between education and psycho-analytic treatment will probably before long be the subject of a detailed investigation. Here I will only give a few hints. One should not be misled by the statement - incidentally a perfectly true one - that the psycho-analysis of an adult neurotic is equivalent to an after-education. A child, even a wayward and delinquent child, is still not a neurotic; and after-education is something quite different from the education of the immature. The possibility of analytic influence rests on quite definite preconditions which can be summed up under the term 'analytic situation'; it requires the development of certain psychical structures and a particular attitude to the analyst. Where these are lacking - as in the case of children, of juvenile delinquents, and, as a rule, of impulsive criminals - something other than analysis must be employed, though something which will be at one with analysis in its *purpose*. The theoretical chapters of the present volume will give the reader a preliminary grasp of the multiplicity of the decisions involved.

I will end with a further inference, and this time one which is important not for the theory of education but for the status of those who are engaged in education. If one of these has learnt analysis by experiencing it on his own person and is in a position of being able to employ it in borderline and mixed cases to assist him in his work, he should obviously be given the right to practise analysis, and narrow-minded motives should not be allowed to try to put obstacles in his way.

JOSEF BREUER
(1925)

Intentionally left blank

4170

JOSEF BREUER

On June 20, 1925, there died in Vienna, in his eighty-fourth year, Josef Breuer, the creator of the cathartic method, whose name is for that reason indissolubly linked with the beginnings of psycho-analysis.

Breuer was a physician, a pupil of the clinician Oppolzer. In his youth he had worked at the physiology of respiration under Ewald Hering, and later, in the scanty hours of leisure allowed by an extensive medical practice, he occupied himself successfully with experiments on the function of the vestibular apparatus in animals. Nothing in his education could lead one to expect that he would gain the first decisive insight into the age-old riddle of the hysterical neurosis and would make a contribution of imperishable value to our knowledge of the human mind. But he was a man of rich and universal gifts, and his interests extended in many directions far beyond his professional activities.

It was in 1880 that chance brought into his hands an unusual patient, a girl of more than ordinary intelligence who had fallen ill of severe hysteria while she was nursing her sick father. It was only some fourteen years later, in our joint publication, *Studies on Hysteria* (1895*d*) - and even then unluckily only in a much abbreviated form, censored, too, from considerations of medical discretion - that the world learnt the nature of his treatment of this celebrated 'first case', with what immense care and patience he carried out the technique when once he had discovered it, till the patient was freed from all the incomprehensible symptoms of her illness, and what insight he obtained in the course of the work into the mental mechanisms of the neurosis.

We psycho-analysts, who have long been familiar with the idea of devoting hundreds of sessions to a single patient, can form no conception of how novel such a procedure must have seemed forty-five years ago. It must have called for a large amount of personal interest and, if the phrase can be allowed, of medical libido, but also for a considerable degree of freedom of thought and certainty of judgement. At the date of the publication of our *Studies* we were able to appeal to Charcot's writings and to Pierre Janet's investigations, which had by that time deprived Breuer's discoveries of some of their priority. But when Breuer was treating his first case (in 1881-2) none of this was as yet available. Janet's *Automatisme psychologique* appeared in 1889 and his second work, *L'état mental des hystériques*, not until 1892. It seems that Breuer's researches were wholly original, and were directed only by the hints offered to him by the material of his case.

I have repeatedly attempted - most recently in my *Autobiographical Study* (1925d), in Grote's series, *Die Medizin der Gegenwart* - to define my share in the *Studies* which we published jointly. My merit lay chiefly in reviving in Breuer an interest which seemed to have become extinct, and in then urging him on to publication. A kind of reserve which was characteristic of him, an inner modesty, surprising in a man of such a brilliant personality, had led him to keep his astonishing discovery secret for so long that not all of it was any longer new. I found reason later to suppose that a purely emotional factor, too, had given him an aversion to further work on the elucidation of the neuroses. He had come up against something that is never absent - his patient's transference on to her physician, and he had not grasped the impersonal nature of the process. At the time when he submitted to my influence and was preparing the *Studies* for publication, his judgement of their significance seemed to be confirmed. 'I believe', he told me, 'that this is the most important thing we two have to give the world.'

Besides the case history of his first patient Breuer contributed a theoretical paper to the *Studies*. It is very far from being out of date; on the contrary, it conceals thoughts and suggestions which have even now not been turned to sufficient account. Anyone immersing himself in this speculative essay will form a true impression of the mental build of this man, whose scientific interests were, alas, turned in the direction of our psychopathology during only one short episode of his long life.

PREFACE TO RAYMOND DE SAUSSURE'S *THE PSYCHO-ANALYTIC METHOD*
(1922)

It is with great pleasure that I am able to assure the public that the present work by Dr. de Saussure is a book of value and merit. It is especially well calculated to give French readers a correct idea of what psycho-analysis is and what it contains.

Dr. de Saussure has not only conscientiously studied my writings, but in addition he has made the sacrifice of coming to me to undergo an analysis lasting several months. This has put him in a position to form his own judgement on the majority of those questions in psycho-analysis which are still undecided, and to avoid the many distortions and errors which one is accustomed to finding in French as well as in German expositions of psycho-analysis. Nor has he failed to contradict certain false or negligent statements which commentators pass on from one to another: such as, for instance, that all dreams have a sexual meaning or that, according to me, the only motive force in our mental life is that of sexual libido.

Since Dr. de Saussure has said in his preface that I have corrected his work, I must add a qualification; my influence has only made itself felt in a few corrections and comments and I have in no way sought to encroach upon the author's independence. In the first, theoretical part of this work, I should have expounded a number of things differently from him: for instance, the difficult topic of the preconscious and the unconscious. And above all, I should have treated the Oedipus complex far more exhaustively.

The excellent dream which Dr. Odier has put at the author's disposal may give even the uninitiated an idea of the wealth of dream-associations and of the relation between the manifest dream-image and the latent thoughts concealed behind it. It demonstrates too the significance that the analysis of a dream can have in the treatment of a patient.

Finally, the remarks which the author makes in conclusion on the technique of psycho-analysis are quite excellent. They are entirely correct and, in spite of their conciseness, leave aside nothing essential. They are convincing evidence of the author's subtle understanding. The reader should not, of course, conclude that knowledge of these rules of technique alone will make him capable of undertaking an analysis.

To-day psycho-analysis is beginning to arouse in a larger measure the interest of professional men and of the lay public in France as well; it will certainly not find any fewer resistances there than it has encountered previously in other countries. Let us hope that Dr. de Saussure's book will make an important contribution to the clarification of the discussions that lie ahead.

FREUD

VIENNA, *February* 1922

PREFACE TO MAX EITINGON'S
REPORT ON THE BERLIN PSYCHO-ANALYTIC POLICLINIC
(MARCH 1920 TO JUNE 1922)
(1923)

My friend Max Eitingon, who created the Berlin Psycho-Analytical Polyclinic and has hitherto supported it out of his own resources, has in the following pages made public his reasons for founding it and has also given an account of the Institute's organization and functions. I can only add to what he has written my wish that individuals or societies may be found elsewhere to follow Eitingon's example and bring similar institutions into existence. If psycho-analysis, alongside of its scientific significance, has a value as a therapeutic procedure, if it is capable of giving help to sufferers in their struggle to fulfil the demands of civilization, this help should be accessible as well to the great multitude who are too poor themselves to repay an analyst for his laborious work. This seems to be a social necessity particularly in our times, when the intellectual strata of the population, which are especially prone to neurosis, are sinking irresistibly into poverty. Institutes such as the Berlin Polyclinic are also alone in a position to overcome the difficulties which otherwise stand in the way of thorough instruction in psycho-analysis. They make possible the education of a considerable number of trained analysts, whose activity must be regarded as the sole possible protection against injury to patients by ignorant and unqualified persons, whether they are laymen or doctors.

LETTER TO FRITZ WITTELS
(1924)

You have given me a Christmas present which is very largely occupied with my own personality. The failure to send a word of thanks for such a gift would be an act of rudeness only to be accounted for by very peculiar motives. Fortunately no such motives exist in this case. Your book is by no means hostile; it is not unduly indiscreet; and it manifests the serious interest in the topic which was to be anticipated in so able a writer as yourself.

I need hardly say that I neither expected nor desired the publication of such a book. It seems to me that the public has no concern with my personality, and can learn nothing from an account of it, so long as my case (for manifold reasons) cannot be expounded without any reserves whatever. But you have thought otherwise. Your own detachment from me, which you consider an advantage, entails serious drawbacks none the less. You know too little of the object of study, and you have not been able to avoid the danger of straining the facts a little in your analytic endeavours. Moreover, I am inclined to think that your adoption of Stekel's standpoint, and the fact that you contemplate the object of study from his outlook, cannot but have impaired the accuracy of your discernment.

In some respects, I think there are positive distortions, and I believe these to be the outcome of a preconceived notion of yours. You think that a great man must have such and such merits and defects, and must display certain extreme characteristics; and you hold that I belong to the category of great men. That is why you ascribe to me all sorts of qualities many of which are mutually conflicting. Much of general interest might be said on this matter, but unfortunately your relationship to Stekel precludes further attempts on my part to clear up the misunderstanding.

On the other hand, I am glad to acknowledge that your shrewdness has enabled you to detect some things which are well known to myself. For instance, you are right in inferring that I have often been compelled to make détours when following my own path. You are right, too, in thinking that I have no use for other people's ideas when they are presented to me at an inopportune moment. (Still, as regards the latter point, I think you might have defended me from the accusation that I am repudiating ideas when I am merely unable for the time being to pass judgement on them or to elaborate them.) But I am delighted to find that you do me full justice in the matter of my relations with Adler....

I realize that you may have occasion to revise your text in view of a second edition. With an eye to this possibility, I enclose a list of suggested emendations. These are based on trustworthy data, and are quite independent of my own prepossessions. Some of them relate to matters of trifling importance, but some of them will perhaps lead you to reverse or modify certain inferences. The fact that I send you these corrections is a token that I value your work though I cannot wholly approve it.

LETTER TO SEÑOR LUIS LOPEZ-BALLESTEROS Y DE TORRES
(1923)

When I was a young student, the desire to read the immortal *Don Quixote* in the original of Cervantes led me to learn, untaught, the lovely Castilian tongue. Thanks to this youthful enthusiasm, I am able to-day - at an advanced age - to test the accuracy of your Spanish version of my works, the reading of which invariably provokes in me a lively appreciation of your very correct interpretation of my thoughts and of the elegance of your style. I am above all astonished that one who, like you, is neither a doctor nor a psychiatrist by profession should have been able to obtain so absolute and precise a mastery over material which is intricate and at times obscure.

LETTER TO *LE DISQUE VERT*
(1924)

Of the many lessons lavished upon me in the past (1885-6) by the great Charcot at the Salpêtrière, two left me with a deep impression: that one should never tire of considering the same phenomena again and again (or of submitting to their effects), and that one should not mind meeting with contradiction on every side provided one has worked sincerely.

FREUD

LETTER TO THE EDITOR OF THE *JEWISH PRESS CENTRE IN ZURICH*
(1925)

. . .I can say that I stand as far apart from the Jewish religion as from all other religions: that is to say, they are of great significance to me as a subject of scientific interest, but I have no part in them emotionally. On the other hand I have always had a strong feeling of solidarity with my fellow-people, and have always encouraged it in my children as well. We have all remained in the Jewish denomination.

In the time of my youth our free-thinking religious instructors set no store by their pupils' acquiring a knowledge of the Hebrew language and literature. My education in this field was therefore extremely behindhand, as I have since often regretted.

ON THE OCCASION OF THE OPENING OF THE HEBREW UNIVERSITY
(1925)

Historians have told us that our small nation withstood the destruction of its independence as a State only because it began to transfer in its estimation of values the highest rank to its spiritual possessions, to its religion and its literature.

We are now living in a time when this people has a prospect of again winning the land of its fathers with the help of a Power that dominates the world, and it celebrates the occasion by the foundation of a University in its ancient capital city.

A University is a place in which knowledge is taught above all differences of religions and of nations, where investigation is carried on, which is to show mankind how far they understand the world around them and how far they can control it.

Such an undertaking is a noble witness to the development to which our people has forced its way in two thousand years of unhappy fortune.

I find it painful that my ill-health prevents me from being present at the opening festivities of the Jewish University in Jerusalem.

EDITORIAL CHANGES IN THE *ZEITSCHRIFT* (1924)

Dr. Otto Rank has acted as editor of this journal ever since its foundation in 1913, even though it is only since 1920 that he has been named on its title-page as sole editor. During his period of military service in the War, his place was taken by Dr. Hanns Sachs, who was at that time in Vienna. Since the beginning of the current volume Dr. S. Ferenczi has also had a share in the editing.

At Easter, 1924, Dr. Rank accepted an invitation which took him to New York. On his return home he announced that he had decided to transfer his activity as a teaching and practising analyst to America - at least for a part of the year. Thus it became necessary to place the editorship of the *Zeitschrift* in other hands. It is not within the rights of the Director to give public expression to his opinion of the level and achievements of this journal. No one who is inclined to appreciate them should overlook or forget how much of its success is due to the tireless devotion and exemplary work of the retiring editor.

Dr. Rank's place will now be taken by Dr. S. Radó of Berlin. He will be supported as advisers and collaborators by Dr. M. Eitingon (Berlin) and Dr. S. Ferenczi (Budapest). All communications and contributions for the editor should be addressed to Dr. Sándor Radó, Berlin-Schöneberg, Am Park, 20. The business side of the *Zeitschrift* will be conducted as before at the offices of the Internationaler Psychoanalytischer Verlag in Vienna (Manager: A. J. Storfer).

AN AUTOBIOGRAPHICAL STUDY
(1925)

Intentionally left blank

AN AUTOBIOGRAPHICAL STUDY

Several of the contributors to this series of 'Autobiographical Studies' have begun by expressing their misgivings at the unusual difficulties of the task they have undertaken. The difficulties in my case are, I think, even greater; for I have already more than once published papers upon the same line as the present one, papers which, from the nature of the subject have dealt more with personal considerations than is usual or than would otherwise have been necessary.

I gave my first account of the development and subject matter of psycho-analysis in five lectures which I delivered in 1909 before Clark University at Worcester, Mass., where I had been invited to attend the celebration of the twentieth anniversary of the foundation of that body.¹ Only recently I gave way to the temptation of making a contribution of a similar kind to an American collective publication dealing with the opening years of the twentieth century, since its editors had shown their recognition of the importance of psycho-analysis by allotting a special chapter to it.² Between these two dates appeared a paper, 'On the History of the Psycho-Analytic Movement', which, in fact, contains the essence of all that I can say on the present occasion. Since I must not contradict myself and since I have no wish to repeat myself exactly, I must endeavour to construct a narrative in which subjective and objective attitudes, biographical and historical interests, are combined in a new proportion.

¹ The lectures were first published (in English) in the *American Journal of Psychology* (1910); the original German was issued under the title of *Über Psychoanalyse*.

² *These Eventful Years* (New York, 1924). My essay, translated by Dr. A. A. Brill, forms chapter lxxiii. of the second volume.

I was born on May 6th, 1856, at Freiberg in Moravia, a small town in what is now Czechoslovakia. My parents were Jews, and I have remained a Jew myself. I have reason to believe that my father's family were settled for a long time on the Rhine (at Cologne), that, as a result of a persecution of the Jews during the fourteenth or fifteenth century, they fled eastwards, and that, in the course of the nineteenth century, they migrated back from Lithuania through Galicia into German Austria. When I was a child of four I came to Vienna, and I went through the whole of my education there. At the 'Gymnasium' I was at the top of my class for seven years; I enjoyed special privileges there, and had scarcely ever to be examined in class. Although we lived in very limited circumstances, my father insisted that, in my choice of a profession, I should follow my own inclinations alone. Neither at that time, nor indeed in my later life, did I feel any particular predilection for the career of a doctor. I was moved, rather, by a sort of curiosity, which was, however, directed more towards human concerns than towards natural objects; nor had I grasped the importance of observation as one of the best means of gratifying it. My deep engrossment in the Bible story (almost as soon as I had learnt the art of reading) had, as I recognized much later, an enduring effect upon the direction of my interest. Under the powerful influence of a school friendship with a boy rather my senior who grew up to be a well-known politician, I developed a wish to study law like him and to engage in social activities. At the same time, the theories of Darwin, which were then of topical interest, strongly attracted me, for they held out hopes of an extraordinary advance in our understanding of the world; and it was hearing Goethe's beautiful essay on Nature read aloud at a popular lecture by Professor Carl Brühl just before I left school that decided me to become a medical student.

When, in 1873, I first joined the University, I experienced some appreciable disappointments. Above all, I found that I was expected to feel myself inferior and an alien because I was a Jew. I refused absolutely to do the first of these things. I have never been able to see why I should feel ashamed of my descent or, as people were beginning to say, of my 'race'. I put up, without much regret, with my non-acceptance into the community; for it seemed to me that in spite of this exclusion an active fellow-worker could not fail to find some nook or cranny in the framework of humanity. These first impressions at the University, however, had one consequence which was afterwards to prove important; for at an early age I was made familiar with the fate of being in the Opposition and of being put under the ban of the 'compact majority'. The foundations were thus laid for a certain degree of independence of judgement.

I was compelled, moreover, during my first years at the University, to make the discovery that the peculiarities and limitations of my gifts denied me all success in many of the departments of science into which my youthful eagerness had plunged me. Thus I learned the truth of Mephistopheles' warning:

Vergebens, dass ihr ringsum wissenschaftlich schweift,
Ein jeder lernt nur, was er lernen kann.

At length, in Ernst Brücke's physiological laboratory, I found rest and full satisfaction - and men, too, whom I could respect and take as my models: the great Brücke himself, and his assistants, Sigmund Exner and Ernst Fleischl von Marxow. With the last of these, a brilliant man, I was privileged to be upon terms of friendship. Brücke gave me a problem to work out in the histology of the nervous system; I succeeded in solving it to his satisfaction and in carrying the work further on my own account. I worked at this Institute, with short interruptions, from 1876 to 1882, and it was generally thought that I was marked out to fill the next post of Assistant that might fall vacant there. The various branches of medicine proper, apart from psychiatry, had no attraction for me. I was decidedly negligent in pursuing my medical studies, and it was not until 1881 that I took my somewhat belated degree as a Doctor of Medicine.

The turning-point came in 1882, when my teacher, for whom I felt the highest possible esteem, corrected my father's generous improvidence by strongly advising me, in view of my bad financial position, to abandon my theoretical career. I followed his advice, left the physiological laboratory and entered the General Hospital as an *Aspirant*. I was soon afterwards promoted to being a *Sekundararzt*, and worked in various departments of the hospital, among others for more than six months under Meynert, by whose work and personality I had been greatly struck while I was still a student.

In a certain sense I nevertheless remained faithful to the line of work upon which I had originally started. The subject which Brücke had proposed for my investigations had been the spinal cord of one of the lowest of the fishes (*Ammocoetes Petromyzon*); and I now passed on to the human central nervous system. Just at this time Flechsig's discoveries of the non-simultaneity of the formation of the medullary sheaths were throwing a revealing light upon the intricate course of its tracts. The fact that I began by choosing the medulla oblongata as the one and only subject of my work was another sign of the continuity of my development. In complete contrast to the diffuse character of my studies during my earlier years at the University, I was now developing an inclination to concentrate my work exclusively upon a single subject or problem. This inclination has persisted and has since led to my being accused of one-sidedness.

I now became as active a worker in the Institute of Cerebral Anatomy as I had previously been in the physiological one. Some short papers upon the course of the tracts and the nuclear origins in the medulla oblongata date from these hospital years, and some notice was taken of my findings by Edinger. One day Meynert, who had given me access to the laboratory even during the times when I was not actually working under him, proposed that I should definitely devote myself to the anatomy of the brain, and promised to hand over his lecturing work to me, as he felt he was too old to manage the newer methods. This I declined, in alarm at the magnitude of the task; it is possible, too, that I had guessed already that this great man was by no means kindly disposed towards me.

From the material point of view, brain anatomy was certainly no better than physiology, and, with an eye to pecuniary considerations, I began to study nervous diseases. There were, at that time, few specialists in that branch of medicine in Vienna, the material for its study was distributed over a number of different departments of the hospital, there was no satisfactory opportunity of learning the subject, and one was forced to be one's own teacher. Even Nothnagel, who had been appointed a short time before, on account of his book upon cerebral localization, did not single out neuropathology from among the other subdivisions of medicine. In the distance shone the great name of Charcot; so I formed a plan of first obtaining an appointment as University Lecturer on Nervous Diseases in Vienna and of then going to Paris to continue my studies.

In the course of the following years, while I continued to work as a junior physician, I published a number of clinical observations on organic diseases of the nervous system. I gradually became familiar with the ground; I was able to localize the site of a lesion in the medulla oblongata so accurately that the pathological anatomist had no further information to add; I was the first person in Vienna to send a case for autopsy with a diagnosis of polyneuritis acuta.

The fame of my diagnoses and of their *post-mortem* confirmation brought me an influx of American physicians, to whom I lectured upon the patients in my department in a sort of pidgin English. About the neuroses I understood nothing. On one occasion I introduced to my audience a neurotic suffering from a persistent headache as a case of chronic localized meningitis; they all quite rightly rose in revolt and deserted me, and my premature activities as a teacher came to an end. By way of excuse I may add that this happened at a time when greater authorities than myself in Vienna were in the habit of diagnosing neurasthenia as cerebral tumour.

In the spring of 1885 I was appointed Lecturer in Neuropathology on the ground of my histological and clinical publications. Soon afterwards, as the result of a warm testimonial from Brücke, I was awarded a Travelling Bursary of considerable value. In the autumn of the same year I made the journey to Paris.

I became a student at the Salpêtrière, but, as one of the crowd of foreign visitors, I had little attention paid me to begin with. One day in my hearing Charcot expressed his regret that since the war he had heard nothing from the German translator of his lectures; he went on to say that he would be glad if someone would undertake to translate the new volume of his lectures into German. I wrote to him and offered to do so; I can still remember a phrase in the letter, to the effect that I suffered only from '*l'aphasie motrice*' and not from '*l'aphasie sensorielle du français*'. Charcot accepted the offer, I was admitted to the circle of his personal acquaintances, and from that time forward I took a full part in all that went on at the Clinic.

As I write these lines, a number of papers and newspaper articles have reached me from France, which give evidence of a violent objection to the acceptance of psycho-analysis, and which often make the most inaccurate assertions in regard to my relations with the French school. I read, for instance, that I made use of my visit to Paris to familiarize myself with the theories of Pierre Janet and then made off with my booty. I should therefore like to say explicitly that during the whole of my visit to the Salpêtrière Janet's name was never so much as mentioned.

What impressed me most of all while I was with Charcot were his latest investigations upon hysteria, some of which were carried out under my own eyes. He had proved, for instance, the genuineness of hysterical phenomena and their conformity to laws (*'introite et hic dii sunt'*), the frequent occurrence of hysteria in men, the production of hysterical paralyses and contractures by hypnotic suggestion and the fact that such artificial products showed, down to their smallest details, the same features as spontaneous attacks, which were often brought on traumatically. Many of Charcot's demonstrations began by provoking in me and in other visitors a sense of astonishment and an inclination to scepticism, which we tried to justify by an appeal to one of the theories of the day. He was always friendly and patient in dealing with such doubts, but he was also most decided; it was in one of these discussions that (speaking of theory) he remarked, *'Ca n'empêche pas d'exister'*, a *mot* which left an indelible mark upon my mind.

No doubt not the whole of what Charcot taught us at that time holds good to-day: some of it has become doubtful, some has definitely failed to withstand the test of time. But enough is left over that has found a permanent place in the storehouse of science. Before leaving Paris I discussed with the great man a plan for a comparative study of hysterical and organic paralyses. I wished to establish the thesis that in hysteria paralyses and anaesthesias of the various parts of the body are demarcated according to the popular idea of their limits and not according to anatomical facts. He agreed with this view, but it was easy to see that in reality he took no special interest in penetrating more deeply into the psychology of the neuroses. When all is said and done, it was from pathological anatomy that his work had started.

Before I returned to Vienna I stopped for a few weeks in Berlin, in order to gain a little knowledge of the general disorders of childhood. Kassowitz, who was at the head of a public institute in Vienna for the treatment of children's diseases, had promised to put me in charge of a department for the nervous diseases of children. In Berlin I was given assistance and a friendly reception by Baginsky. In the course of the next few years I published, from the Kassowitz Institute, several monographs of considerable size on unilateral and bilateral cerebral palsies in children. And for that reason, at a later date (in 1897), Nothnagel made me responsible for dealing with the same subject in his great *Handbuch der allgemeinen und speziellen Therapie*.

In the autumn of 1886 I settled down in Vienna as a physician, and married the girl who had been waiting for me in a distant city for more than four years. I may here go back a little and explain how it was the fault of my *fiancée* that I was not already famous at that youthful age. A side interest, though it was a deep one, had led me in 1884 to obtain from Merck some of what was then the little-known alkaloid cocaine and to study its physiological action. While I was in the middle of this work, an opportunity arose for making a journey to visit my *fiancée*, from whom I had been parted for two years. I hastily wound up my investigation of cocaine and contented myself in my monograph on the subject with prophesying that further uses for it would soon be found. I suggested, however, to my friend Königstein, the ophthalmologist, that he should investigate the question of how far the anaesthetizing properties of cocaine were applicable in diseases of the eye. When I returned from my holiday I found that not he, but another of my friends, Carl Koller (now in New York), whom I had also spoken to about cocaine, had made the decisive experiments upon animals' eyes and had demonstrated them at the Ophthalmological Congress at Heidelberg. Koller is therefore rightly regarded as the discoverer of local anaesthesia by cocaine, which has become so important in minor surgery; but I bore my *fiancée* no grudge for the interruption.

I will now return to the year 1886, the time of my settling down in Vienna as a specialist in nervous diseases. The duty devolved upon me of giving a report before the 'Gesellschaft der Aerzte' upon what I had seen and learnt with Charcot. But I met with a bad reception. Persons of authority, such as the chairman (Bamberger, the physician), declared that what I said was incredible. Meynert challenged me to find some cases in Vienna similar to those which I had described and to present them before the Society. I tried to do so; but the senior physicians in whose departments I found any such cases refused to allow me to observe them or to work at them. One of them, an old surgeon, actually broke out with the exclamation: 'But, my dear sir, how can you talk such nonsense? *Hysteron (sic)* means the uterus. So how can a man be hysterical?' I objected in vain that what I wanted was not to have my diagnosis approved, but to have the case put at my disposal. At length, outside the hospital, I came upon a case of classical hysterical hemi-anaesthesia in a man, and demonstrated it before the 'Gesellschaft der Aerzte'. This time I was applauded, but no further interest was taken in me. The impression that the high authorities had rejected my innovations remained unshaken; and, with my hysteria in men and my production of hysterical paralyses by suggestion, I found myself forced into the Opposition. As I was soon afterwards excluded from the laboratory of cerebral anatomy and for terms on end had nowhere to deliver my lectures, I withdrew from academic life and ceased to attend the learned societies. It is a whole generation since I have visited the 'Gesellschaft der Aerzte'.

Anyone who wants to make a living from the treatment of nervous patients must clearly be able to do something to help them. My therapeutic arsenal contained only two weapons, electrotherapy and hypnotism, for prescribing a visit to a hydropathic establishment after a single consultation was an inadequate source of income. My knowledge of electrotherapy was derived from W. Erb's text-book, which provided detailed instructions for the treatment of all the symptoms of nervous diseases. Unluckily I was soon driven to see that following these instructions was of no help whatever and that what I had taken for an epitome of exact observations was merely the construction of phantasy. The realization that the work of the greatest name in German neuropathology had no more relation to reality than some 'Egyptian' dream-book, such as is sold in cheap book-shops, was painful, but it helped to rid me of another shred of the innocent faith in authority from which I was not yet free. So I put my electrical apparatus aside, even before Moebius had saved the situation by explaining that the successes of electric treatment in nervous disorders (in so far as there were any) were the effect of suggestion on the part of the physician.

With hypnotism the case was better. While I was still a student I had attended a public exhibition given by Hansen the 'magnetist', and had noticed that one of the subjects experimented upon had become deathly pale at the onset of cataleptic rigidity and had remained so as long as that condition lasted. This firmly convinced me of the genuineness of the phenomena of hypnosis. Scientific support was soon afterwards given to this view by Heidenhain; but that did not restrain the professors of psychiatry from declaring for a long time to come that hypnotism was not only fraudulent but dangerous and from regarding hypnotists with contempt. In Paris I had seen hypnotism used freely as a method for producing symptoms in patients and then removing them again. And now the news reached us that a school had arisen at Nancy which made an extensive and remarkably successful use of suggestion, with or without hypnosis, for therapeutic purposes. It thus came about, as a matter of course, that in the first years of my activity as a physician my principal instrument of work, apart from haphazard and unsystematic psychotherapeutic methods, was hypnotic suggestion.

This implied, of course, that I abandoned the treatment of organic nervous diseases; but that was of little importance. For on the one hand the prospects in the treatment of such disorders were in any case never promising, while, on the other hand, in the private practice of a physician working in a large town, the quantity of such patients was nothing compared to the crowds of neurotics, whose number seemed further multiplied by the way in which they hurried, with their troubles unsolved, from one physician to another. And, apart from this, there was something positively seductive in working with hypnotism. For the first time there was a sense of having overcome one's helplessness; and it was highly flattering to enjoy the reputation of being a miracle-worker. It was not until later that I was to discover the drawbacks of the procedure. At the moment there were only two points to complain of: first, that I could not succeed in hypnotizing every patient, and secondly, that I was unable to put individual patients into as deep a state of hypnosis as I should have wished. With the idea of perfecting my hypnotic technique, I made a journey to Nancy in the summer of 1889 and spent several weeks there. I witnessed the moving spectacle of old Liébeault working among the poor women and children of the labouring classes. I was a spectator of Bernheim's astonishing experiments upon his hospital patients, and I received the profoundest impression of the possibility that there could be powerful mental processes which nevertheless remained hidden from the consciousness of men. Thinking it would be instructive, I had persuaded one of my patients to follow me to Nancy. This patient was a very highly gifted hysteric, a woman of good birth, who had been handed over to me because no one knew what to do with her. By hypnotic influence I had made it possible for her to lead a tolerable existence and I was always able to take her out of the misery of her condition. But she always relapsed again after a short time, and in my ignorance I attributed this to the fact that her hypnosis had never reached the stage of somnambulism with amnesia. Bernheim now attempted several times to bring this about, but he too failed. He frankly admitted to me that his great therapeutic successes by means of suggestion were only achieved in his hospital practice and not with his private patients. I had many stimulating conversations with him, and undertook to translate into German his two works upon suggestion and its therapeutic effects.

During the period from 1886 to 1891 I did little scientific work, and published scarcely anything. I was occupied with establishing myself in my new profession and with assuring my own material existence as well as that of a rapidly increasing family. In 1891 there appeared the first of my studies on the cerebral palsies of children, which was written in collaboration with my friend and assistant, Dr. Oskar Rie. An invitation which I received in the same year to contribute to an encyclopaedia of medicine led me to investigate the theory of aphasia. This was at the time dominated by the views of Wernicke and Lichtheim, which laid stress exclusively upon localization. The fruit of this enquiry was a small critical and speculative book, *Zur Auffassung der Aphasien*

But I must now show how it happened that scientific research once more became the chief interest of my life.

II

I must supplement what I have just said by explaining that from the very first I made use of hypnosis in *another* manner, apart from hypnotic suggestion. I used it for questioning the patient upon the origin of his symptom, which in his waking state he could often describe only very imperfectly or not at all. Not only did this method seem more effective than mere suggestive commands or prohibitions, but it also satisfied the curiosity of the physician, who, after all, had a right to learn something of the origin of the phenomenon which he was striving to remove by the monotonous procedure of suggestion.

The manner in which I arrived at this other procedure was as follows. While I was still working in Brücke's laboratory I had made the acquaintance of Dr. Josef Breuer, who was one of the most respected family physicians in Vienna, but who also had a scientific past, since he had produced several works of permanent value upon the physiology of respiration and upon the organ of equilibrium. He was a man of striking intelligence and fourteen years older than myself. Our relations soon became more intimate and he became my friend and helper in my difficult circumstances. We grew accustomed to share all our scientific interests with each other. In this relationship the gain was naturally mine. The development of psycho-analysis afterwards cost me his friendship. It was not easy for me to pay such a price, but I could not escape it.

Even before I went to Paris, Breuer had told me about a case of hysteria which, between 1880 and 1882, he had treated in a peculiar manner which had allowed him to penetrate deeply into the causation and significance of hysterical symptoms. This was at a time, therefore, when Janet's works still belonged to the future. He repeatedly read me pieces of the case history, and I had an impression that it accomplished more towards an understanding of neuroses than any previous observation. I determined to inform Charcot of these discoveries when I reached Paris, and I actually did so. But the great man showed no interest in my first outline of the subject, so that I never returned to it and allowed it to pass from my mind.

When I was back in Vienna I turned once more to Breuer's observation and made him tell me more about it. The patient had been a young girl of unusual education and gifts, who had fallen ill while she was nursing her father, of whom she was devotedly fond. When Breuer took over her case it presented a variegated picture of paralyses with contractures, inhibitions and states of mental confusion. A chance observation showed her physician that she could be relieved of these clouded states of consciousness if she was induced to express in words the affective phantasy by which she was at the moment dominated. From this discovery, Breuer arrived at a new method of treatment. He put her into deep hypnosis and made her tell him each time what it was that was oppressing her mind. After the attacks of depressive confusion had been overcome in this way, he employed the same procedure for removing her inhibitions and physical disorders. In her waking state the girl could no more describe than other patients how her symptoms had arisen, and she could discover no link between them and any experiences of her life. In hypnosis she immediately discovered the missing connection. It turned out that all her symptoms went back to moving events which she had experienced while nursing her father; that is to say, her symptoms had a meaning and were residues or reminiscences of those emotional situations. It was found in most instances that there had been some thought or impulse which she had had to suppress while she was by her father's sick-bed, and that, in place of it, as a substitute for it, the symptom had afterwards appeared. But as a rule the symptom was not the precipitate of a single such 'traumatic' scene, but the result of a summation of a number of similar situations. When the patient recalled a situation of this kind in a hallucinatory way under hypnosis and carried through to its conclusion, with a free expression of emotion, the mental act which she had originally suppressed, the symptom was abolished and did not return. By this procedure Breuer succeeded, after long and painful efforts, in relieving his patient of all her symptoms.

The patient had recovered and had remained well and, in fact, had become capable of doing serious work. But over the final stage of this hypnotic treatment there rested a veil of obscurity, which Breuer never raised for me; and I could not understand why he had so long kept secret what seemed to me an invaluable discovery instead of making science the richer by it. The immediate question, however, was whether it was possible to generalize from what he had found in a single case. The state of things which he had discovered seemed to me to be of so fundamental a nature that I could not believe it could fail to be present in any case of hysteria if it had been proved to occur in a single one. But the question could only be decided by experience. I therefore began to repeat Breuer's investigations with my own patients and eventually, especially after my visit to Bernheim in 1889 had taught me the limitations of hypnotic suggestion, I worked at nothing else. After observing for several years that his findings were invariably confirmed in every case of hysteria that was accessible to such treatment, and after having accumulated a considerable amount of material in the shape of observations analogous to his, I proposed to him that we should issue a joint publication. At first he objected vehemently, but in the end he gave way, especially, since, in the meantime, Janet's works had anticipated some of his results, such as the tracing back of hysterical symptoms to events in the patient's life, and their removal by means of hypnotic reproduction in *statu nascendi*. In 1893 we issued a preliminary communication, 'On the Psychical Mechanism of Hysterical Phenomena', and in 1895 there followed our book, *Studies on Hysteria*.

If the account I have so far given has led the reader to expect that the *Studies on Hysteria* must, in all essentials of their material content, be the product of Breuer's mind, that is precisely what I myself have always maintained and what it has been my aim to repeat here. As regards the *theory* put forward in the book, I was partly responsible, but to an extent which it is to-day no longer possible to determine. That theory was in any case unpretentious and hardly went beyond the direct description of the observations. It did not seek to establish the nature of hysteria but merely to throw light upon the origin of its symptoms. Thus it laid stress upon the significance of the life of the emotions and upon the importance of distinguishing between mental acts which are unconscious and those which are conscious (or rather capable of being conscious); it introduced a dynamic factor, by supposing that a symptom arises through the damming-up of an affect, and an economic factor, by regarding that same symptom as the product of the transformation of an amount of energy which would otherwise have been employed in some other way. (This latter process was described as *conversion*.) Breuer spoke of our method as *cathartic*; its therapeutic aim was explained as being to provide that the quota of affect used for maintaining the symptom, which had got on to the wrong lines and had, as it were, become strangulated there, should be directed on to the normal path along which it could obtain discharge (or *abreaction*). The practical results of the cathartic procedure were excellent. Its defects, which became evident later, were those of all forms of hypnotic treatment. There are still a number of psychotherapists who have not gone beyond catharsis as Breuer understood it and who still speak in its favour. Its value as an abridged method of treatment was shown afresh by Simmel in his treatment of war neuroses in the German army during the Great War. The theory of catharsis had not much to say on the subject of sexuality. In the case histories which I contributed to the *Studies* sexual factors played a certain part, but scarcely more attention was paid to them than to other emotional excitations. Breuer wrote of the girl, who has since become famous as his first patient, that her sexual side was extraordinarily undeveloped. It would have been difficult to guess from the *Studies on Hysteria* what an importance sexuality has in the aetiology of the neuroses.

The stage of development which now followed, the transition from catharsis to psycho-analysis proper, has been described by me several times already in such detail that I shall find it difficult to bring forward any new facts. The event which formed the opening of this period was Breuer's retirement from our common work, so that I became the sole administrator of his legacy. There had been differences of opinion between us at quite an early stage, but they had not been a ground for our separating. In answering the question of when it is that a mental process becomes pathogenic - that is, when it is that it becomes impossible for it to be dealt with normally - Breuer preferred what might be called a physiological theory: he thought that the processes which could not find a normal outcome were such as had originated during unusual, 'hypnoid', mental states. This opened the further question of the origin of these hypnoid states. I, on the other hand, was inclined to suspect the existence of an interplay of forces and the operation of intentions and purposes such as are to be observed in normal life. Thus it was a case of 'hypnoid hysteria' versus 'neuroses of defence'. But such differences as this would scarcely have alienated him from the subject if there had not been other factors at work. One of these was undoubtedly that his work as a physician and family doctor took up much of his time, and that he could not, like me, devote his whole strength to the work of catharsis. Again, he was affected by the reception which our book had received both in Vienna and in Germany. His self-confidence and powers of resistance were not developed so fully as the rest of his mental organization. When, for instance, the *Studies* met with a severe rebuff from Strümpell, I was able to laugh at the lack of comprehension which his criticism showed, but Breuer felt hurt and grew discouraged. But what contributed chiefly to his decision was that my own further work led in a direction to which he found it impossible to reconcile himself.

The theory which we had attempted to construct in the *Studies* remained, as I have said, very incomplete; and in particular we had scarcely touched on the problem of aetiology, on the question of the ground in which the pathogenic process takes root. I now learned from my rapidly increasing experience that it was not *any* kind of emotional excitation that was in action behind the phenomena of neurosis but habitually one of a sexual nature, whether it was a current sexual conflict or the effect of earlier sexual experiences. I was not prepared for this conclusion and my expectations played no part in it, for I had begun my investigation of neurotics quite unsuspectingly. While I was writing my 'History of the Psycho-Analytic Movement' in 1914, there recurred to my mind some remarks that had been made to me by Breuer, Charcot, and Chrobak, which might have led me to this discovery earlier. But at the time I heard them I did not understand what these authorities meant; indeed they had told me more than they knew themselves or were prepared to defend. What I heard from them lay dormant and inactive within me, until the chance of my cathartic experiments brought it out as an apparently original discovery. Nor was I then aware that in deriving hysteria from sexuality I was going back to the very beginnings of medicine and following up a thought of Plato's. It was not until later that I learnt this from an essay by Havelock Ellis.

Under the influence of my surprising discovery, I now took a momentous step. I went beyond the domain of hysteria and began to investigate the sexual life of the so-called neurasthenics who used to visit me in numbers during my consultation hours. This experiment cost me, it is true, my popularity as a doctor, but it brought me convictions which to-day, almost thirty years later, have lost none of their force. There was a great deal of equivocation and mystery-making to be overcome, but, once that had been done, it turned out that in all of these patients grave abuses of the sexual function were present. Considering how extremely widespread are these abuses on the one hand and neurasthenia on the other, a frequent coincidence between the two would not have proved much; but there was more in it than that one bald fact. Closer observation suggested to me that it was possible to pick out from the confused jumble of clinical pictures covered by the name of neurasthenia two fundamentally different types, which might appear in any degree of mixture but which were nevertheless to be observed in their pure forms. In the one type the central phenomenon was the anxiety attack with its equivalents, rudimentary forms and chronic substitutive symptoms; I consequently gave it the name of *anxiety neurosis*, and limited the term *neurasthenia* to the other type. Now it was easy to establish the fact that each of these types had a different abnormality of sexual life as its corresponding aetiological factor: in the former, *coitus interruptus*, unconsummated excitation and sexual abstinence, and in the latter, excessive masturbation and too numerous nocturnal emissions. In a few specially instructive cases, which had shown a surprising alteration in the clinical picture from one type to the other, it could be proved that there had been a corresponding change in the underlying sexual régime. If it was possible to put an end to the abuse and allow its place to be taken by normal sexual activity, a striking improvement in the condition was the reward.

I was thus led into regarding the neuroses as being without exception disturbances of the sexual function, the so-called '*actual neuroses*' being the direct toxic expression of such disturbances and the *psychoneuroses* their mental expression. My medical conscience felt pleased at my having arrived at this conclusion. I hoped that I had filled up a gap in medical science, which, in dealing with a function of such great biological importance, had failed to take into account any injuries beyond those caused by infection or by gross anatomical lesions. The medical aspect of the matter was, moreover, supported by the fact that sexuality was not something purely mental. It had a somatic side as well, and it was possible to assign special chemical processes to it and to attribute sexual excitation to the presence of some particular, though at present unknown, substances. There must also have been some good reason why the true spontaneous neuroses resembled no group of diseases more closely than the phenomena of intoxication and abstinence, which are produced by the administration or privation of certain toxic substances, or than exophthalmic goitre, which is known to depend upon the product of the thyroid gland.

Since that time I have had no opportunity of returning to the investigation of the '*actual neuroses*'; nor has this part of my work been continued by anyone else. If I look back to-day at my early findings, they strike me as being the first rough outlines of what is probably a far more complicated subject. But on the whole they seem to me still to hold good. I should have been very glad if I had been able, later on, to make a psycho-analytic examination of some more cases of simple juvenile neurasthenia, but unluckily the occasion did not arise. To avoid misconceptions, I should like to make it clear that I am far from denying the existence of mental conflicts and of neurotic complexes in neurasthenia. All that I am asserting is that the symptoms of these patients are not mentally determined or removable by analysis, but that they must be regarded as direct toxic consequences of disturbed sexual chemical processes.

During the years that followed the publication of the *Studies*, having reached these conclusions upon the part played by sexuality in the aetiology of the neuroses, I read some papers on the subject before various medical societies, but was only met with incredulity and contradiction. Breuer did what he could for some time longer to throw the great weight of his personal influence into the scales in my favour, but he effected nothing and it was easy to see that he too shrank from recognizing the sexual aetiology of the neuroses. He might have crushed me or at least disconcerted me by pointing to his own first patient, in whose case sexual factors had ostensibly played no part whatever. But he never did so, and I could not understand why this was, until I came to interpret the case correctly and to reconstruct, from some remarks which he had made, the conclusion of his treatment of it. After the work of catharsis had seemed to be completed, the girl had suddenly developed a condition of '*transference love*'; he had not connected this with her illness, and had therefore retired in dismay. It was obviously painful to him to be reminded of this apparent *contretemps*. His attitude towards me oscillated for some time between appreciation and sharp criticism; then accidental difficulties arose, as they never fail to do in a strained situation, and we parted.

Another result of my taking up the study of nervous disorders in general was that I altered the technique of catharsis. I abandoned hypnotism and sought to replace it by some other method, because I was anxious not to be restricted to treating hysteriform conditions. Increasing experience had also given rise to two grave doubts in my mind as to the use of hypnotism even as a means to catharsis. The first was that even the most brilliant results were liable to be suddenly wiped away if my personal relation with the patient became disturbed. It was true that they would be re-established if a reconciliation could be effected; but such an occurrence proved that the personal emotional relation between doctor and patient was after all stronger than the whole cathartic process, and it was precisely that factor which escaped every effort at control. And one day I had an experience which showed me in the crudest light what I had long suspected. It related to one of my most acquiescent patients, with whom hypnotism had enabled me to bring about the most marvellous results, and whom I was engaged in relieving of her suffering by tracing back her attacks of pain to their origins. As she woke up on one occasion, she threw her arms round my neck. The unexpected entrance of a servant relieved us from a painful discussion, but from that time onwards there was a tacit understanding between us that the hypnotic treatment should be discontinued. I was modest enough not to attribute the event to my own irresistible personal attraction, and I felt that I had now grasped the nature of the mysterious element that was at work behind hypnotism. In order to exclude it, or at all events to isolate it, it was necessary to abandon hypnotism.

But hypnotism had been of immense help in the cathartic treatment, by widening the field of the patient's consciousness and putting within his reach knowledge which he did not possess in his waking life. It seemed no easy task to find a substitute for it. While I was in this perplexity there came to my help the recollection of an experiment which I had often witnessed while I was with Bernheim. When the subject awoke from the state of somnambulism, he seemed to have lost all memory of what had happened while he was in that state. But Bernheim maintained that the memory was present all the same; and if he insisted on the subject remembering, if he asseverated that the subject knew it all and had only to say it, and if at the same time he laid his hand on the subject's forehead, then the forgotten memories used in fact to return, hesitatingly at first, but eventually in a flood and with complete clarity. I determined that I would act in the same way. My patients, I reflected, must in fact 'know' all the things which had hitherto only been made accessible to them in hypnosis; and assurances and encouragement on my part, assisted perhaps by the touch of my hand, would, I thought, have the power of forcing the forgotten facts and connections into consciousness. No doubt this seemed a more laborious process than putting the patients into hypnosis, but it might prove highly instructive. So I abandoned hypnotism, only retaining my practice of requiring the patient to lie upon a sofa while I sat behind him, seeing him, but not seen myself.

III

My expectations were fulfilled; I was set free from hypnotism. But along with the change in technique the work of catharsis took on a new complexion. Hypnosis had screened from view an interplay of forces which now came in sight and the understanding of which gave a solid foundation to my theory.

How had it come about that the patients had forgotten so many of the facts of their external and internal lives but could nevertheless recollect them if a particular technique was applied? Observation supplied an exhaustive answer to these questions. Everything that had been forgotten had in some way or other been distressing; it had been either alarming or painful or shameful by the standards of the subject's personality. It was impossible not to conclude that that was precisely why it had been forgotten - that is, why it had not remained conscious. In order to make it conscious again in spite of this, it was necessary to overcome something that fought against one in the patient; it was necessary to make efforts on one's own part so as to urge and compel him to remember. The amount of effort required of the physician varied in different cases; it increased in direct proportion to the difficulty of what had to be remembered. The expenditure of force on the part of the physician was evidently the measure of a *resistance* on the part of the patient. It was only necessary to translate into words what I myself had observed, and I was in possession of the theory of *repression*.

It was now easy to reconstruct the pathogenic process. Let us keep to a simple example, in which a particular impulsion had arisen in the subject's mind but was opposed by other powerful impulsions. We should have expected the mental *conflict* which now arose to take the following course. The two dynamic quantities - for our present purposes let us call them 'the instinct' and 'the resistance' - would struggle with each other for some time in the fullest light of consciousness, until the instinct was repudiated and the cathexis of energy withdrawn from its impulsion. This would have been the normal solution. In a neurosis, however (for reasons which were still unknown), the conflict found a different outcome. The ego drew back, as it were, on its first collision with the objectionable instinctual impulse; it debarred the impulse from access to consciousness and to direct motor discharge, but at the same time the impulse retained its full cathexis of energy. I named this process *repression*; it was a novelty, and nothing like it had ever before been recognized in mental life. It was obviously a primary mechanism of defence, comparable to an attempt at flight, and was only a forerunner of the later-developed normal condemning judgement. The first act of repression involved further consequences. In the first place the ego was obliged to protect itself against the constant threat of a renewed advance on the part of the repressed impulse by making a permanent expenditure of energy, an *anticathexis*, and it thus impoverished itself. On the other hand, the repressed impulse, which was now *unconscious*, was able to find means of discharge and of substitutive satisfaction by circuitous routes and thus to bring the whole purpose of the repression to nothing. In the case of conversion hysteria the circuitous route led to the somatic innervation; the repressed impulse broke its way through at some point or other and produced *symptoms*. The symptoms were thus results of a compromise, for although they were substitutive satisfactions they were nevertheless distorted and deflected from their aim owing to the resistance of the ego.

The theory of repression became the corner-stone of our understanding of the neuroses. A different view had now to be taken of the task of therapy. Its aim was no longer to 'abreact' an affect which had got on to the wrong lines but to uncover repressions and replace them by acts of judgement which might result either in the accepting or in the condemning of what had formerly been repudiated. I showed my recognition of the new situation by no longer calling my method of investigation and treatment *catharsis* but *psycho-analysis*.

It is possible to take repression as a centre and to bring all the elements of psycho-analytic theory into relation with it. But before doing so I have a further comment of a polemical nature to make. According to Janet's view a hysterical woman was a wretched creature who, on account of a constitutional weakness, was unable to hold her mental acts together, and it was for that reason that she fell a victim to a splitting of her mind and to a restriction of the field of her consciousness. The outcome of psycho-analytic investigations, on the other hand, showed that these phenomena were the result of dynamic factors - of mental conflict and of repression. This distinction seems to me to be far-reaching enough to put an end to the glib repetition of the view that whatever is of value in psycho-analysis is merely borrowed from the ideas of Janet. The reader will have learned from my account that historically psycho-analysis is completely independent of Janet's discoveries, just as in its content it diverges from them and goes far beyond them. Janet's works would never have had the implications which have made psycho-analysis of such importance to the mental sciences and have made it attract such universal interest. I always treated Janet himself with respect, since his discoveries coincided to a considerable extent with those of Breuer, which had been made earlier but were published later than his. But when in the course of time psycho-analysis became a subject of discussion in France, Janet behaved ill, showed ignorance of the facts and used ugly arguments. And finally he revealed himself to my eyes and destroyed the value of his own work by declaring that when he had spoken of 'unconscious' mental acts he had meant nothing by the phrase - it had been no more than a *façon de parler*.

But the study of pathogenic repressions and of other phenomena which have still to be mentioned compelled psycho-analysis to take the concept of the 'unconscious' seriously. Psycho-analysis regarded everything mental as being in the first instance unconscious; the further quality of 'consciousness' might also be present, or again it might be absent. This of course provoked a denial from the philosophers, for whom 'conscious' and 'mental' were identical, and who protested that they could not conceive of such an absurdity as the 'unconscious mental'. There was no help for it, however, and this idiosyncrasy of the philosophers could only be disregarded with a shrug. Experience (gained from pathological material, of which the philosophers were ignorant) of the frequency and power of impulses of which one knew nothing directly, and whose existence had to be inferred like some fact in the external world, left no alternative open. It could be pointed out, incidentally, that this was only treating one's own mental life as one had always treated other people's. One did not hesitate to ascribe mental processes to other people, although one had no immediate consciousness of them and could only infer them from their words and actions. But what held good for other people must be applicable to oneself. Anyone who tried to push the argument further and to conclude from it that one's own hidden processes belonged actually to a second *consciousness* would be faced with the concept of a consciousness of which one knew nothing, of an 'unconscious consciousness' - and this would scarcely be preferable to the assumption of an 'unconscious mental'. If on the other hand one declared, like some other philosophers, that one was prepared to take pathological phenomena into account, but that the processes underlying them ought not to be described as mental but as 'psychoïd', the difference of opinion would degenerate into an unfruitful dispute about words, though even so expediency would decide in favour of keeping the expression 'unconscious mental'. The further question as to the ultimate nature of this unconscious is no more sensible or profitable than the older one as to the nature of the conscious.

It would be more difficult to explain concisely how it came about that psycho-analysis made a further distinction in the unconscious, and separated it into a *preconscious* and an unconscious proper. It will be sufficient to say that it appeared a legitimate course to supplement the theories that were a direct expression of experience with hypotheses that were designed to facilitate the handling of the material and related to matters which could not be a subject of immediate observation. The very same procedure is adopted by the older sciences. The subdivision of the unconscious is part of an attempt to picture the apparatus of the mind as being built up of a number of *agencies* or *systems* whose relations to one another are expressed in spatial terms, without, however, implying any connection with the actual anatomy of the brain. (I have described this as the *topographical* method of approach.) Such ideas as these are part of a speculative superstructure of psycho-analysis, any portion of which can be abandoned or changed without loss or regret the moment its inadequacy has been proved. But there is still plenty to be described that lies closer to actual experience.

I have already mentioned that my investigation of the precipitating and underlying causes of the neuroses led me more and more frequently to conflicts between the subject's sexual impulses and his resistances to sexuality. In my search for the pathogenic situations in which the repressions of sexuality had set in and in which the symptoms, as substitutes for what was repressed, had had their origin, I was carried further and further back into the patient's life and ended by reaching the first years of his childhood. What poets and students of human nature had always asserted turned out to be true: the impressions of that early period of life, though they were for the most part buried in amnesia, left ineradicable traces upon the individual's growth and in particular laid down the disposition to any nervous disorder that was to follow. But since these experiences of childhood were always concerned with sexual excitations and the reaction against them, I found myself faced by the fact of *infantile sexuality* - once again a novelty and a contradiction of one of the strongest of human prejudices. Childhood was looked upon as 'innocent' and free from the lusts of sex, and the fight with the demon of 'sensuality' was not thought to begin until the troubled age of puberty. Such occasional sexual activities as it had been impossible to overlook in children were put down as signs of degeneracy or premature depravity or as a curious freak of nature. Few of the findings of psycho-analysis have met with such universal contradiction or have aroused such an outburst of indignation as the assertion that the sexual function starts at the beginning of life and reveals its presence by important signs even in childhood. And yet no other finding of analysis can be demonstrated so easily and so completely.
